Dairy prepotency and beef prepotency are qualities which move in diametrically opposite directions. No man ever developed dairy qualities in the coming offspring by breeding to strong beef heredity, nor *vice versa*. Yet, there is not a so-called dual-purpose Short-horn or Red Poll bull in existence which does not show clear and unmistakable beef heredity in both form and pedigree. If he begets a good milker she is a sport, and in four cases out of five as a rule she will not in turn produce profitable milkers. But even if the cow would breed towards dairy quality, if well mated, where will we go to find a dual-purpose sire with sufficient dairy heredity in him to reinforce the desired tendency in the cow? Looked at either as a matter of breeding science or for profitable dairy results, the breeding for dual-purpose is, we believe, a myth, which no well posted dairy farmer can afford to indulge in for reasons that he can spend his money and time to much larger purpose and profit.

The Latest Silo Suggestion.

ED. HOARD'S DAIRYMAN:—Do you think the plan for a silo submitted herewith to be practical? We would like your opinion and also that of the subscribers to your most valuable paper. Silo to be 14×30, built in barn, of fir timber, well seasoned and well tarred 1×3 strips dressed to a bevel, so when nailed together flatwise, they will make a 14-foot circle and the wall will be 3 inches thick, and nailed with 8d. nails, each nail penetrating the third strip, and hooped with ⅝ round iron, a good foundation, and floored with Portland cement.

Sumas, Wash. W. H. R. & SON.

A silo built as suggested would probably be all right, but certainly no better than one built of thicker lumber or one built of ordinary 2×4's. We question very much whether the beveling suggested would be of any benefit whatever. Indeed, we think the chances are that it would be a detriment because of the impossibility of securing a uniform bevel. The amount to be taken off of each strip would be only one-thirtieth of an inch and it would be very difficult, not to say impossible, to run the pieces through any machine so as to secure just this amount of cut, and no more, throughout the entire length of the strip. As indicated above, we do not consider the three-inch wall any advantage. Indeed, the silo on the farm of the present writer, standing out without any protection whatever from the weather, in a climate quite as severe as any that can be found in the state of Washington, has walls only a scant inch and one-half thick and we have yet to observe any indication that this thickness of wall is not as satisfactory as any other, provided the lumber is of proper quality. In our own case we used selected cypress lumber, primarily, because we could not get, at the time, in our local lumber yards, any pine or hemlock that was reasonably free from shakes and sap. Although the cypress cost us us $40 per thousand, we are inclined to believe that it was a more economic purchase, all things considered, than it would have been to pay $15 or $20 for either pine or hemlock.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

Feeding Value of Alfalfa Hay.

Will you kindly give me some information regarding alfala hay. I find I can buy it delivered at my place for $18.60 per ton. It comes from the far west. I am short of pasturing and have to depend on soiling crops. Can I afford to feed alfalfa at the above price, and would it enable me to cut my grain ration any, either summer or winter? When good, clover mixed hay is worth $16 here, would alfalfa be more profitable to buy at $18.60? Grain costs us about as follows:

Gluten, $32 per ton; bran, $23; corn meal, $24; oats, $47. We send our milk to Boston; average price for six months, 26½c per 8½ qt. can.

Warren, Mass. H. M. C.

Very much will depend on the quality of the alfalfa hay shipped in from the far west. Perhaps as good a way to judge of quality, in the absence of chemical analysis, would be to observe whether the leaves are still adherent to the stem or whether a goodly portion of them have been lost. In the latter case, the probabilities are, either that the alfalfa was too ripe when cut, or that it was more or less damaged in curing, and in either event, is of inferior quality.

The following table gives the percentages of digestible nutrients in the several feedstuffs mentioned, when of average quality:

Alfalfa hay	52.8
Clover hay	46.4
Mixed clover and timothy	48.0
Ground corn	84.3
Gluten feed	80.1
Gluten meal	78.9
Oats	66.0
Bran	58.0

From this table it will appear that one pound of ground corn contains as much digestible nutriment as one and one-half pounds of bran, and five per cent more than gluten feed. Corn is therefore much the cheapest of the grain feeds mentioned and it is also the most natural complement to alfalfa hay. The only difficulty is that it is seldom profitable to feed ground corn alone as it is so concentrated that much of it is apt to be undigested. It should therefore be diluted with chopped feed of some kind, or with bran, or oats. On the mere basis of contained nutriment, a mixed clover and timothy hay at $16 per ton is a trifle cheaper than alfalfa at $18.60, but the alfalfa hay carries so much more protein that it would probably be a cheaper feed to go with soiling crops than the mixed hay, and this more especially, if the alfalfa is of good quality.

Variation in Cream Test.

Will you please tell me if the test of cream for April should be about the same as for March, where the conditions are as near the same as it is possible to make them? The same cows, same feed, milked by same persons, same separator run in same manner, no change in cream screw. Also should cream shipped every day test less than when shipped twice per week? My cream tested 12 points less in April than in March.

Longford, Kas. A. D. A.

There is no regularity in the quality of cream from month to month. The amount of fat present may be higher or lower than the preceding month, and no reason can be given for the same, nor any indication as to how much change there would be. Moreover, it is impossible to keep the conditions the same from month to month. If nothing else is changed the cow is always a varying factor, both in amount and quality of milk produced. A dairyman who sells milk or cream should always have the apparatus to test his products. He would gain much important knowledge that would be useful in his business. Cream should test the same whether shipped every day or once in several days.

A New York Ration.

Please give me a balanced ration from the following feeds:

XXXX distiller s dried grains at $24 a ton; bran, $17; Buffalo gluten feed, $21; good corn silage, well eared, with good hay, half clover and half timothy. Cows largely in full flow of milk. Would it be advisable to feed entirely of distiller s grains? H. A.

Williamson, N. Y.

There is not much to choose between the dried grains mentioned and gluten feed at the prices stated in the above communication. The dried grains carry approximately ninety per cent of digestible nutrients and gluten feed eighty per cent. We consider either of these feeds cheaper than bran at $17. It is our judgment that a daily allowance of four pounds of gluten feed and two pounds of the dried grains, fed half at night and half in the morning, with a teaspoonful of salt at each feeding, with what silage and hay the cows will care to eat, will furnish a very satisfactory ration. We do not specify the precise amount of silage and the precise amount of hay as these must be regulated very largely by the amounts available. If there is silage enough to make it profitable to carry something over for summer feeding, we should feed the silage quite sparingly. On the other hand, if there is but little silage left, we should feed more liberally, and in any event, feed all the hay the cows will eat without waste.

Time for Seeding Mangles—Oats—Corn for Silo.

I want to plant 2 acres of mangles or cow beets. When is the best time to plant and how far apart should the rows be and the best way to keep them for winter?

About how late in the season will it do to seed oats to harvest and thresh?

About when shall I plant corn for silo?

Racine, Wis. G. S. K.

It has been demonstrated over and over again, that the best way to raise mangles is to plant the field to corn. More feed and better feed can be raised in this way than by growing root crops. However, if this correspondent is disposed to grow the beets, let him plant the seed whenever the ground can be put in good condition. The rows should be far enough apart so that they can be cultivated by machinery. It is not an easy matter to store a large amount of beets for winter use. They must be kept away from the frost, but must not be kept in too warm a cellar, and must be provided with proper ventilation; which are additional reasons why Wisconsin farmers should prefer to raise corn for silage rather than roots of any kind.

It is already so late in the season that the present writer has concluded not to sow any more oats but rather devote the land to corn. It is quite possible that oats sown at this time, or even later, might ripen, but the chances are that the severe heat and drought would cut the yield down very materially.

We should expect to get a good crop of corn for silage planted in this latitude as late as the 10th of June, provided, the ground was in proper condition at time of planting. We should, of course, prefer to plant earlier, if conditions warranted it.

What Grain With Pasture.

I am interested in dairyIng and would like your advice on the feeding question. I have a dairy of ten cows, and send the milk to a company creamery where the milk is tested and I am paid according to the amount of butter fat. I have never fed grain. Would it pay me to buy oil meal at $23.50 per ton and other grain to balance the ration and feed my cows during the summer? If so, what grains would you advise me to buy and what ration to feed twice a day? I am a reader of your DAIRYMAN and am well pleased with it.

Otter Lake, Mich. H. S. W,

When pastures are at their best, it is doubtful whether feeding of grain is especially profitable, but unfortunately, they are not at their best except for a very few weeks, and then, in our judgment, it does pay to feed more or less grain, the amount to be determined largely by the kind of cows kept and their condition as to lactation. Enough grain or other material should be fed to prevent any undue shrinkage, for when shrinkage is once established, it is difficult, if not impossible, to again bring up the milk flow.

It is perhaps an open question whether good hay in connection with good pasturage is not equally as efficient as grain. We consider a mixture of bran and ground corn or ground corn and oats a very satisfactory feed to supplement the pastures.

A Plastered Silo

I want to build a silo by setting up studs and lath and plaster with cement. How will I manage with the hoops? Won't those hoops break lath and cement if put them on top? How much will I save by putting up one like this, or concrete silo, and which do you think best? P. W. B.

Naumburg, N. Y.

In answer to the above inquiry and for the information of others who may not have read it last year, we republish in this issue, Mr. Gurler's description of the manner of building a silo, with inner surface of cement plaster. Not only Mr. Gurler, but others who have had experience with silos, are of the opinion that this form of silo is not only the cheapest, where durability is considered, but is also the most effective in providing an air-proof structure.

What Grain to Feed with Soiling Crops—Corn or Sorghum—Saving Alfalfa Seed.

In order to get best results from cows, what kind of grain ration would you advise feeding while soiling this summer? Bran, $16; oats, $20, and corn, $21.40 or possibly more. Won't clear bran be the most profitable?

Do you consider sugar cane an improvement over corn in any respect for fodder or soiling? Can it be drilled with an ordinary corn planter, or will it be too thick?

I am trying to get a stand of alfalfa. I got 20 lbs. of seed from the Department of Agriculture at Washington, furnished free with the understanding that I am to save the seed and sell back to them. I sowed it over two acres with a thin nurse crop on high clay soil. If I get a stand I will report results. Does alfalfa ever bear seed in this section, and if so, what crop? Would you advise sowing alone or with a nurse crop?

Oshkosh, Wis. R. F. M.

See the answer to H. M. C., of Warren, Mass., in this issue, for a statement as to the relative feeding values of bran, oats and corn. The kind of grain to be selected to feed with soiling crops will depend very largely upon the kind of soiling crops available. With clover, or alfalfa, or oats and peas, a mixture of one-third bran and two-thirds corn would be perhaps about right. If the soiling crops consisted of rye, or green corn, or other highly carbonaceous foods, a mixture of bran and oats, or bran and gluten feed, would be more appropriate. We do not consider sorghum an improvement over corn in any respect for fodder or soiling except that it has a reputation of standing the drought much better than corn; but these are questions that have been so frequently considered in these columns, in recent issues, that it does not seem profitable to go over the ground again.

Reasoning from analogy, we should expect the third crop of alfalfa to furnish the most and the best seed, but what amount can be expected to the acre in this climate has not been as yet determined by experience.

What to Feed Dairy Cows?

Would you please advise me through your valuable paper what feed to feed to dairy cows to obtain best results, and also give me a balanced ration for same? I am a new subscriber and like your paper very much.

Dayton, Ohio.

It is one of the fortunate things connected with dairying, that one is not limited, even for best results, to any particular line or class of feeds, but can use very largely whatever he can best produce on his farm, or can exchange at good profit farm-grown products for different kinds of commercial feeds. When there is such a wide latitude for choice, it is impracticable for us to even suggest to this inquirer what would be the best feeds for him either to raise or to buy, but if he will tell us what kinds of feeds he has on hand or can procure, we shall be very glad to offer such suggestions as the situation may seem to make most opportune.

Moldy Silage.

What is the cause of moldy spots in otherwise perfect silage? Round silo, new. Spots in the center, mostly six inches in diameter, tapering to nothing up and down, perfect all around above and below. M. B. D.

Such spots of mold in center of silage usually come from the corn being too dry when put in silo. The trouble can be obviated by a thorough wetting of the silage after the silo is filled.

Butter Fat in Milk.

ED. HOARD'S DAIRYMAN:—How much butter fat is there in 647 pounds of milk testing 4.10 and 447 pounds testing 3.80, and how much butter would it churn? What would be the average?

A READER.

Marshfield, Wis.

In the 647 lbs. of 4.10 milk, there will be 26.5 pounds of fat, which with ⅛ overrun, will make 29.8 pounds of butter. In the 447 pounds of 3.8% milk, there will be 16.98 pounds of fat, making 19 1 pounds of butter. The above butter yield is theoretical, the actual creamery returns may be a little above or below these figures.

The Minimum Amount of Protein in a Ration.

ED. HOARD'S DAIRYMAN:—In studying the results of last winter's work in our experiments on nutrient requirements in milk production, I find almost identical results as reported in Bulletin 79 when similar methods of making comparisons are employed, but by making total digestible matter consumed daily, a basis instead of net nutriment, as was done in Bulletin 79, it appears that the ration containing a low per cent of protein was not as effective as was the one containing more protein. The same results are obtained with the work of the herd for the winter of 1901-2, if similar methods of comparison are employed.

To illustrate, let us take the total digestible matter consumed daily and butter fat yielded daily by the two groups of cows receiving the most and least protein each year as a basis:

YEAR.	*Protein.*	*Total Digestible matter daily.*	*Butter fat daily.*	*Digestible matter to 1 lb. butter fat.*
1901-2	2.04	14.36	1.260	11.40
1901-2	1.32	13.58	1.182	11.48
1902-3	2.02	14.18	1 050	13.50
1902-3	1.24	12.27	.900	13.62

From this it will be seen that by disregarding the food of maintenance the group of cows receiving the most protein, both winters, returned a pound of butter fat for a trifle less nutriment than did the group receiving less protein.

This gives the results exactly as they are obtained without attempting to account for the nutriment used for product and that converted to maintenance. The fact that the group receiving 2.04 pounds of protein and 14.36 pounds of total nutriment daily maintained 890 pounds of body weight and returned a pound of butter fat to 11.40 pounds of nutriment, while the group receiving 1.32 pounds protein and 13 58 pounds of total nutriment daily maintained 846 pounds of body weight and returned a pound of butter fat to 11.48 pounds of nutriment, gives evidence that the former ration was the more effective.

The same is the case with the work done last winter when the group receiving 2.02 pounds of protein and 14.18 lbs. of total nutriment daily, maintained a body weight of 878 pounds and returned a pound of butter fat to 13.50 pounds of nutriment consumed, while the group receiving 1.24 pounds of protein and 12.27 pounds of total nutriment daily maintained 825 pounds of body weight and returned a pound of butter fat to 13.62 lbs. of nutriment consumed. While the difference in nutriment required to a pound of butter fat is small, the testimony is quite strong, because of the large number of cows employed, and because when the least amount of protein was fed, the difference in the nutriment required to a pound of butter fat was the greatest.

The small amount of nutriment required to a pound of butter fat by both groups in 1901-2 is accounted for by the fact that both groups lost in body weight during the winter, while during the winter 1902-3 their normal body weight was maintained.

The group of cows that received 1.32 pounds of protein daily, weighed 846 lbs. and had therefore at the rate of 1.56 lbs. of protein per 1,000 pounds live weight, and those that received 1.24 pounds of protein in the winter following, weighed 825 pounds and had at the rate of 1.50 pounds of protein daily. The minimum amount of protein for normal work is therefore above 1.50 pounds per 1,000 pounds live weight.

It seems quite likely that the table submitted on page 104 in bulletin 79, is very close to the actual requirements, when vigorous vitality is to be maintained, foetal growth to be provided for and a maximum yield secured. This practically called for a ration containing a nutritive ratio of from 1:6.5 to 1:7.5, dependent upon the flow of milk and weight of cow. At least for the time being, a wider ration is not recommended.

It will be seen that each year the group of cows that received the larger protein supply maintained greater weight of body and produced butter fat with less nutriment.

Minnesota Experiment Station.

Saving and Using Liquid Manure.

ED. HOARD'S DAIRYMAN:—I have noted the questions asked by A. B. C. in your issue for Feb. 15 in relation to liquid manure and what to do with it, also what you have to say in reply.

Will you permit me to add a little to what has been said? There is a farm a few miles away on which the urine from the stable has been used for several years with excellent results. There is a large new barn with basement stables—all above ground, having cement floors so constructed as to discharge the urine in the center underneath, where there is a capacious cistern. In applying this liquid, a large tank made for the purpose is placed on a wagon or sled, and filled directly from the cistern with a good-sized pump, and is so arranged as to discharge it evenly on the land where wanted. It is mostly put on grass land. This has to be done when there is snow on the ground to prevent injury to the grass. A light snow is all that is needed. It can be put on plowed land at any time when not occupied with crops.

The effects thus far have been very satisfactory, causing a large production of grass and hay. Last year where this liquid and manure from a hog pen having a cement floor were used side by side on grass, the difference between the two was plainly visible, so much so as to excite remarks from the neighbors. Where the liquid was applied, the results were decidedly the best. This certainly shows that there was considerable virtue in this kind of fertilizer, and in such available form as to produce quick and good results. It is possible that the effects from stable manure might be more lasting than the liquid.

It is possible, if there could be sufficient absorbents used to retain all of the liquids, that this would be the better way to dispose of them, but I am satisfied that this would require a water-tight floor and a large amount of material to be used as absorbents.

Previous to the present winter, plank floors have been used in the stables of the writer. The cows have been bedded

"ADVERTISEMENT."

DON'T STAY SICK

When a Postal Will Bring You Help.

Write me today, for each day's delay means a day more of ill-health. Just tell me which book to send.

I will mail you an order—good at any drug store—for six bottles Dr. Shoop's Restorative. You may take it a month on trial. If it succeeds, the cost is $5.50. If it fails, I will pay the druggist myself—and your mere word shall decide it.

While you are waiting, thousands of others are cured. Out of each 40 who make this month's test, there are 39 who pay for it gladly, because they get well. I willingly pay for the rest.

You don't need to have faith in me. I have the faith, for I know the remedy; and I take the risk. Won't you simply try to get well?

I have spent a lifetime in learning how to strengthen weak inside nerves. My Restorative brings back that power which alone operates the vital organs. I treat a weak organ as I would a weak engine, by giving it the power to act. My way always succeeds, save when a cause like cancer makes a cure impossible. And most of these chronic diseases cannot be cured without it.

You'll know this when you read my book.

Simply state which book you want, and address Dr. Shoop, Box 934, Racine, Wis.

Book No. 1 on Dyspepsia.
Book No. 2 on the Heart.
Book No. 3 on the Kidneys.
Book No. 4 for Women.
Book No. 5 for Men (sealed)
Book No. 6 on Rheumatism

Mild cases, not chronic, are often cured by one or two bottles. At all druggists.

A GREAT COMBINATION!

GOOD COWS AND A U.S. SEPARATOR FILL THE FARMER'S POCKETS WITH MONEY!

The U. S. Separator gets all the cream from the milk,
The cream makes the butter,
The skim-milk makes the calf,
All bring in the cash.

twice a day with cut straw, which should add to its efficiency in absorbing liquids, yet despite this a considerable portion of the liquid passed through the floor between the planks and was practically lost.

Last season a cement floor was put in, along with two cisterns, to catch the liquids, if these were not all absorbed with the cut straw. Although the straw has been used as freely as before, yet there is a large portion of the liquid that passes into the cistern.

As this is our first experience with this kind of fertilizer used alone, will have to wait until after harvest to judge more particularly of its effects upon the grass-land, to which it is being applied. Shall expect a favorable response however. There is some satisfaction to us eastern farmers in being able to save and utilize the entire amount of the manure product, whether solid or liquid.

I wish here to say a word in favor of running the straw or other coarse material to be used for bedding, through a fodder cutter.

Where there is the necessary machinery on the farm for the purpose, the expense of cutting will be very small, and it will be found that the cut straw is much better for bedding, as it can be applied more evenly, goes farther, absorbs more of the liquid and adds to the ease and convenience in handling.

We feed no straw, but all is used for bedding, and a large amount is required for the horses, cows, pigs and other young animals.

But there is much satisfaction in finding that the supply of manure is being materially "extended" from the practice, and that the land is growing richer and the crops more abundant, and this is the doctrine the DAIRYMAN is persistently trying to inculcate into the minds and methods of its readers. E. R. TOWLE.

Progressive Education at the Prince Edward Island Dairy School.

Butter Making Discussions.—Some Pointers About Furnishing Clean Milk.

ED. HOARD'S DAIRYMAN:—The Dairy School opened at Charlottetown last week with a large attendance of students, principally Island cheese and butter makers. The school is in charge of Prof. Zufelt of Ontario and Provincial Inspector Morrow. There are over one hundred and fifty cheese makers in the Island. Only about one-third of them have however attended the course.

Following are notes on one of the lectures delivered by the professor, who in the words of Prof. Robertson, presented hitching posts for the thoughts of his hearers.

MILK FOR CHEESE FACTORIES AND CREAMERIES.

The cheese or butter maker's success will largely depend on his ability to get milk free of all injurious germs. The character of the milk determines the character of the cheese or butter; therefore the absolute necessity of having a first-class quality of raw material. The quality of the milk is influenced by:

1. The individuality and health of the cow.
2. The food, water, soil, etc.
3. Bacterial infection.

Milk is a product manufactured directly from the blood. Anything which affects the blood affects the milk.

Milk from diseased cows or cows in poor health should always be rejected.

Flavors produced by food, etc., are distinguished from bacterial flavors by the fact that food flavors are always most pronounced at the time of milking, while, on the other hand, the flavors produced by bacteria may not be perceptible at first, but gradually grow worse. Bacterial influences are the hardest to counteract and most to be feared. The milk from a healthy cow fed on good, wholesome food, is comparatively free from all germ life.

The first source of infection is at the time of milking, either from the cow's body or from the surroundings. Use, therefore, precautionary measures rather than curative. Cleanliness, sunlight and pure air are our most effective weapons in fighting bacterial taints.

PRECAUTIONARY MEANS.

All utensils should be thoroughly washed and scalded and kept in the open air in direct sunlight, in a place free from all dust and bad odors.

Have the cow's body, especially the udder and flanks, thoroughly brushed and cleaned and wiped off with a clean, damp cloth before milking. The milking should be done in a clean place, free of dust, and with clean hands. If the milking is done in the stable or barn yard, have it removed as quickly as possible.

Bacteria develop fastest at a temperature from 80° to 100° F., and are almost entirely dormant at 50° F. One single germ under favorable conditions will produce in 24 hours, 16 million. Milk may also be contaminated by keeping it too near the barn yards, stables, pig pens, under trees, by the road side, or any place where dust or bad odors abound. Old, leaky milk cans, filthy strainer cloths, and general uncleanliness are prolific sources of contamination.

Milk may also be affected by the condition of the factories, such as dirty whey tanks, bad drainage, bad water, bad floors, and flies, which act as a medium of conveying the filth germs to the vats.

1. Cleanliness is absolutely essential.
2. Do the milking in as cleanly a manner as possible, in a clean place, free of dust and bad odors.
3. Use a strainer more as a precaution than a necessity.
4. Wash all pails, strainers, etc., thoroughly and then scald.
5. Cool the milk, especially in warm weather, to below 60°.
6. Keep the milk in a clean place, free of all contaminating influences.

P. E. I. J. A. M.

The General-Purpose.

ED. HOARD'S DAIRYMAN:—I have been reading so much lately about general-purpose cows, general-purpose barns, general-purpose horses, general-purpose men and etc., that I am anxious to learn more about this general-purpose, and, if possible, get into the seed of it, if it does not come too high. Now, the first thing is a general-purpose barn. We are having a new railroad built near us, and there is much trouble about us getting a depot, and I would like a barn to keep my cows and feed in and at the same time use it for a waiting room and depot and possibly run a small hotel in it too. Please give instruction how to build a general-purpose barn.

Next, we have been out of a trusty driving horse for some time and the last one smashed up the buggy, and as my mower is getting old, I thought I would get a general-purpose mower, and as it was in use only a few days in the year, we could use it for an automobile.

We have a DeLaval separator that has given us splendid satisfaction as a skimmer for the last five years, but our sewing machine is played out. If I could trade this separator for a general-purpose one and then use it for a sewing machine, it surely would be a great saving. I don't see why these general-purpose manufacturers do not advertise more. I have seen some general-purpose barn plans, but upon examination I found they were intended expressly for diversified farming and were as especially built for that, as a cow barn or depot. There is a lot more of these general-purpose articles I want but will not mention them now but wait until I find those named. R. CLAWSON.

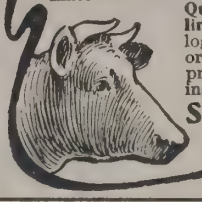
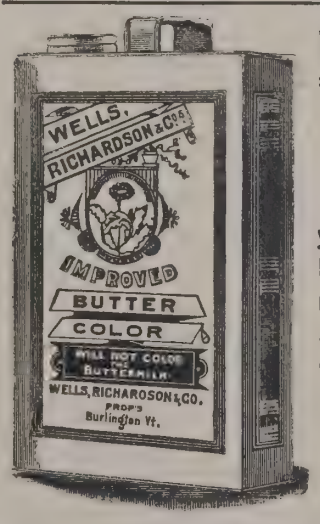
The BOYD CREAM RIPENER



STURGES & BURN MFG. CO. CHICAGO

Wherever it has been introduced unqualified endorsements come, both from amateurs and experienced butter makers, upon "THE BOYD." It places cream ripening perfectly within the control of all, and reduces it to mathematical precision. Finer and more uniform flavors are the sure results. It possesses double the insulating properties and double the cooling surface of any other machine. Its cream distributor, affording rapid cooling and thorough aeration, all unite in making it the



Standard Cream Ripener of America.

We publish a special catalogue, our No. 12, devoted entirely to a description of this matchless machine. We mail it free upon request. We also manufacture the **Dairy Queen Churn, Standard Milk Cans, Cheese Apparatus and a general line of Creamery Machinery and Milk Dealers' Supplies.** Special catalogues for different lines. We are connected in no way with any trust or combination, and devote ourselves to supplying at reasonable prices, every article applicable to the creamery business. Write stating your needs, and we will mail free appropriate catalogue.

Conversion Factor for Estimating the Yield of Butter from the Amount of Fat in Milk—Sensible Conclusions by the Holstein-Friesian Register.

In its issue for May, 1903, the *Holstein-Friesian Register*, discusses the relation of butter fat in the milk to standard commercial butter, as follows:

The Associated Experiment Stations, through Prof. F. W. Woll, of the Wisconsin Station, have called the attention of our Association to what they consider as defects in our rules for official tests. As given by Mr. Hoxie, the changes which they suggest are three in number; the most important of which relates to the per cent of fat which shall be considered equivalent to a pound of butter. The original rule adopted by the Holstein-Friesian Association made 83⅓ per cent of one pound of butter fat, as found in the milk by the Babcock test, equivalent to one pound of finished butter; and this rule stood till the Annual Meeting of '94. By this rule one-fifth was added to the amount of butter fat produced by the cow to determine the amount of butter with which she should be credited.

At that time the rule was perfectly fair, butter being more heavily salted and not worked so dry as at present; butter containing 82½ per cent fat being considered of high grade.

There has been much dispute as to whether or not the rule of 80 per cent of a pound of fat equivalent to a pound of butter really was established at the World's Fair in Chicago in '93, those denying it claiming that Chief Buchanan changed the rules in the heifer test in the interests of economy, and for that reason only. But that plea is rather technical than correct; for while the rules did require that all comparisons of cows should be made on the basis of 80 per cent of a pound of fat in the churned butter equivalent to one pound of estimated butter, in test No. 4, or the heifer test, the rule was set aside, and 80 per cent of one pound of butter fat in the milk taken as the equivalent of one pound of butter.

Also, in making his report to the Exposition Committee and the Jersey Cattle Club, Mr. Valancey E. Fuller, superintendent of the Jersey Herd, in all instances where the butter was not actually churned, and where he wishes to make comparisons, uses the formula of 80 per cent of a pound of butter fat in the milk equivalent to a pound of butter.

Again, as the losses of butter fat with good work are slight, it may well be claimed that there is no very great difference between taking 80 per cent of a lb. of fat in the churned butter, or 80 per cent of a pound of fat in the original milk, as a basis to work from.

In order to put our records in harmony with those of other breeds, as thus established at the World's Fair in Chicago, so as to make comparisons possible, at the annual meeting of '94 our standard was changed to the 80 per cent rule, and has so remained since; something like 2,000 records having been made under the rule. By the 80 per cent rule, ¼ is added to the amount of fat given by the cow to determine the amount of butter with which she shall be credited.

During the ten years since the World's Fair of '93 there has been a wonderful growth of the dairy industry; innumerable creameries have been established, and there has been a corresponding growth in our dairy schools. The establishment of the thousands of creameries has made it possible to make millions of pounds of high grade butter of uniform quality; the dairy schools are teaching how to make it; while the creamery supply houses vie with one another in furnishing the most improved machinery to make it with; and all this makes it possible to turn out immense quantities of the best quality of butter which shall grade practically alike. Numberless analyses have shown that such high grade butter contains very close to 85 per cent fat; whereas at Chicago the churned butter was turned into estimated butter on a basis of 80 per cent fat.

It has also been learned, and is now well known to every posted man, that with the best work and the best machinery the loss of butter fat in butter making is small, and that 85.7 per cent of a pound of butter fat will make about one pound of butter 85 per cent pure fat. This is called the 85.7 standard; by which one-sixth is added to the amount of butter fat given by the cow to determine the amount of butter with which she shall be credited.

The criticism of the Holstein-Friesian standard of 80 per cent fat began many years ago, and has been a sore point with many of us, as something we could not defend. Our honored Superintendent of Advanced Registry, always on guard to protect Holstein-Friesian interests, noting this criticism, at the annual meeting at Buffalo in 1899, asked and obtained permission from the Board of Officers to make his computations of butter for the Advanced Registry both by the 80 per cent and by the 87.5 per cent rules; and for the last four years the Holstein Friesian Association has had virtually a double standard. But, while all records have been given officially to the press under the double standard, within the association, and unofficially writing for the press, we have recognized only the 80 per cent rule, and the criticism is growing more vigorous. An article is just now going through the dairy press credited to the *New York Farmer*, concerning Sadie Vale Concordia, our greatest cow. It starts off, "The thirty-pounds-of-butter-a-week cow has arrived. And further down it states that, "The record will be accepted the world over, because it is not a private record, but is made under the vigilant supervision of a representative of Cornell University." Thus, coupling the two things together, from the standpoint of the Experiment Stations it makes them vouch for the alleged fact of the great cow having made over thirty lbs. butter; whereas they will not admit that she made any such amount. In fact, it has got to the point where a great dairy paper, published in Wisconsin, virtually holds the Experiment Stations as *particeps criminis* in deceiving the public; and the stations are becoming restive.

The Holstein-Friesian breeders wish to deceive no one, and would spurn any intimation that they have any use for false pretenses of any kind. The great desire of the association is to make its system of official testing perfect; and we cannot think it will be found backward in taking any advance step required.

To those of us who have hundreds of records, as now computed, on our tongue's end, it will be a task to learn them all over again; but if this must be done, and the records already made scaled down, the sooner the change is made, the better. A matter of this kind cannot be settled for good till it is settled right; and the right in this case evidently is the computing of 85.7 per cent of one pound of butter fat in the milk as equivalent to one pound of finished butter.

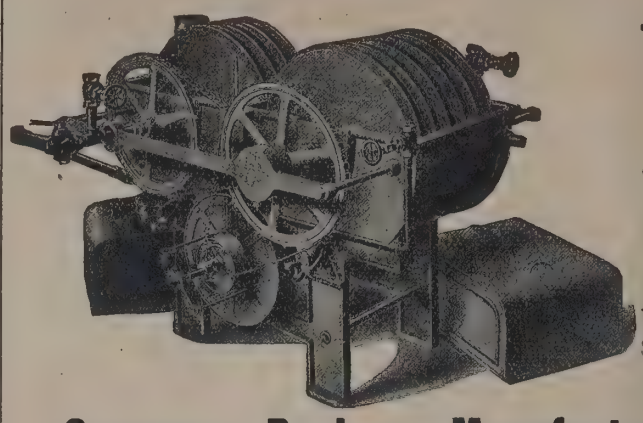
The Combined Corn and Cow Pea Planter Invented.—What Crop to Follow Rye.

ED. HOARD'S DAIRYMAN:—Will you please advise me what to plant or sow on land, after the rye has been harvested for grain, to produce winter forage for dairy cows? I thought of planting an early variety of sweet corn, and if cow peas would mature, or get of any size, it would improve the forage. Any suggestion will be appreciated.

Since seeing your article in DAIRYMAN of April 24th, page 249, in regard to a combined corn and cow pea planter, I have invented a machine that will drill or plant in hills as wanted, both corn and peas in the same row and at the one operation.

The expense of manufacturing will be but little more than ordinary planters as it consists of only two extra hoppers and plates and two small sprockets attached to common corn planters.

I intend trying to interest the manufacturers of planters to put this on the market so that it can be used for the season of 1904, and believe if there is a demand sufficient to justify, they will do so.



Wishing the DAIRYMAN and all concerned, success. E. B. P.

Moorhead, Iowa.

Depending somewhat upon the time the rye is cut off, we see no reason why our correspondent may not raise a very fair crop of corn and cow peas. In this vicinity, corn planted quite late in June, frequently comes forward and makes a very good crop, and cow peas should come to maturity in about ninety days.

In the matter of a combined corn and cow pea planter, our correspondent seems to have worked along lines identical with those which have suggested themselves to us. There would seem to be no reason in the world why the addi-

ILLUSTRATION.

THE "HARTMAN" FENCE.

We are presenting herewith a cut of the standard and well known Hartman Stockade Farm Fencing. This fence, which was formerly manufactured by the Hartman Mfg. Co., of Elwood City, Pa., is now being made by the Cuyahoga Wire and Fence Co., Cuyahoga Falls, Ohio. We feel that this fence has been so favorably known to our readers for so long a time that we need to say little in commendation of it at this time This fence is made in four different styles and of various heights and is suited to all special and general farm uses for fencing against hogs, sheep, cattle and horses. A slight examination of the cut will show how thoroughly well the fence is made and how unusually strong it must be. The "Hartman" is an entirely interwoven fence and has no loose ends at top and bottom to unravel or to injure stock from projecting loose ends. The very manner of the weaving is such as to insure perfect expansion and contraction and even adjustment to all weather conditions. The price is very reasonable also, when the extra good qualities of the fence are considered. It is doubtful, indeed, if the same amount of money can be expended in any way by the farmer or land owner that will make such a desirable showing or so much improve and add to the value of property as in the purchase of good fencing. Those who seek all the desired qualities of a good and permanent fence and one which will at the same time add to the neatless and beauty of every enclosure, should correspond with the manufacturers of the "Hartman" fence. Ask them for a catalogue and other information about their goods and kindly mention that you saw this in HOARD'S DAIRYMAN.

YORKSHIRES A few choice imported Boars. September farrow. Also pigs from imported stock ready for delivery in 8 weeks. W. H. FISHER, Spahr Bldg, Columbus, O

tional hoppers could not be added to the planter and so geared with the other machinery as to plant alternately corn and peas.

DAIRY MARKETS.

ELGIN, Ill., May 11—Butter rulled firm on the board of trade to-day, selling at 21c. The sales for the week were 670,000 lbs.

CHICAGO, Ill., May 11—Butter—Firm; creameries, 17@21c; dairies, 14½@18c.

Eggs—Firmer; at mark, cases included, 14½@14¾c.

Cheese—New steady; Twins, 13@13¼c; Daisies, 13@13⅛c; Young Americas, 13⅛c.

Cattle—Prime beeves, 1,200 to 1,400 pounds, 5.40@5.65; choice to extra beeves, 5.10@5.40; fair to good export and shipping steers, 4.60@5.00; medium beef steers, 4.40@4.60; plain beef steers, 4.00@4.50; common to rough, 1,000 to 1,200 lbs. 3.50@3.90; good to choice feeders, 4.10@5.10; good to choice heifers, 3.90@4.60; poor to plain stockers and feeders, 2.75@4.00; fair to good cows and heifers, 3.20@4.20; good cutting and fair beef cows, 2.60@3.15; common to good canning cows 1.50@2.50; bulls, poor to choice, 2.50@4.40; veal calves, good to fancy, 5.25@6.25; calves, common to fancy, 3.50@5.00; corn-fed western steers, 3.65@5.40; Texas bulls and grass steers, 2.75@3.20; Texas steers, fair to common, 3.75@4.60.

Hogs—Good to prime heavy shipping 6.75@6.85; good to choice heavy packing 6.65@6.80; plain to choice heavy mixed 6.60@6.75; selected butcher weights 6.70@6.85; assorted light, 150 to 195 lbs. 6.45@6.65; common to good light mixed, 6.35@6.55; thin to choice, 50 to 130 lbs., lots 6.05@6.40; stags to rough lots, 3.75@6.05.

MILWAUKEE, Wis., May 11—Butter—Creamery—extras, 20c; firsts, 18c; seconds, 16c; process (renovated), 16@17c; whey, 10c. Dairy, fancy, 18c; lines, fresh, 15@16c; roll, 15@16c; packing, 13c; grease, 5@6c.

Cheese—American, new, full cream, Twins, 13@13½c; Young Americas, 13@13½c: Daisies, 14@14½c; Longhorns, 13@13½c; low grades, 10@12c. Brick, fancy, new, 13@13½c; low grades, 11@12c. Limburger, fancy, new, 11½@12c; low grades, 8@9c. Swiss, drum, old, choice, 15½@16c; drum, No. 2, 13@14c; Block, choice, 14@14½c; block, No. 2, 12@13c.

Eggs—Strictly fresh laid, cases returned, 13½c; dirties, 12c; seconds, 11c.

PLYMOUTH, May 5—Cheese — Eighteen factories offered 1,067 boxes cheese and all sold as follows: 263 Longhorns, 13¾c; 433 Daisies, 14½c; 258 Twins, 13½c; 86 Americas, 13¼; 27 Americas, 13⅜c. Market active and firm.

BRILLION, Wis., Apr. 30—Cheese—The sales were: 206 Daisies; 39 Twins and 5 cases Young Americas all at 13c.

HORTONVILLE, Wis., April 30—Cheese—The offerings all sold as follows: 116 Twins at 12¾c; 33 Twins at 14c.

APPLETON, Wis., April 30—Cheese—Eight factories offered 190 boxes of Twins and all sold at 12¾c. Next meeting May 14 at 2 p. m.

SHEBOYGAN FALLS, Wis., May 6—Cheese—24 factories offered 1,357 boxes of cheese on the Call Board today and all sold as follows: 70 Twins at 13⅜c; 127 cases Young Americas at 13⅜c; 95 at 13¼c; 24 at 13½c; 220 Daisies at 14¼c; 54 cases Longhorns, at 13⅜c; 726 at 13⅜c; 43 at 13½c. Market active and firm.

SHEBOYGAN, Wis., May 6—Cheese—On the Sheboygan Call Board today the offerings and sales comprised 1,061 boxes of cheese. Sales were as follows: 10 boxes Twins at 13c; 10 Daisies at 14c; 467 at 14¼c; 50 at 14⅜c; 64 cases Young Americas at 13c; 50 at 13¼c; 291 cases Longhorns at 13¾c; 110 at 13⅜c. Market slightly weaker.

FOND DU LAC, Wis., May 11—Cheese—Sales at the Dairy Board today were 145 Daisies at 14¼c; 70 at 14⅜c, and 35 Twins at 12¾c; 32 Twins withdrawn. Market active.

BOSTON, Mass., May 11 — Butter — Western creamery, 22@22½c: western firsts, 21½c; dairy, 16@20c; imitation creamery, 16@19c; ladle, 14@15c; box and print, 15@23c.

Cheese—Choice, 14½c; sage, 14c; Wisconsin new, 12½@12¾c; fair to good, 9@10¼c.

Eggs—Near by, 20c; Western selected, 16½c; 16½c; fair to good, 15@16c.

UTICA, N. Y., May 11—Market active, but holders sell freely. Sales, 9,500; small 11¼c, large 11c, curb ¼c higher.

NEW YORK, May 11—Butter—Receipts, 4,642 lbs.; market firm; creamery, extra, 22c; creamery, common to choice, 18@21½c; state dairy, 17@21c.

Cheese—Receipts, 1,028 lbs.; market steady; state full cream, fancy, small, colored and white, old, 13@15c; large, colored and white, old, 13@14¾c; small, colored and white, new, 12c; large, colored and white, new, 11¾c.

Eggs—Receipts, 16,012 packages; weak; state and Pennsylvania, 17c; Kentucky, 16½c; western storage packed, 17c; western firsts, 16½@17c; southern, 15½@16c.

KANSAS CITY, May 11.—Butter—Creamery, 17@20; dairy, 17c.

Eggs—Steady; fresh Missouri and Kansas stock, 12½c doz. cases returned; new No. 2 white wood cases included, 13c.

WASHINGTON, D. C. May 11—Butter—Market very firm and bare. Extras, 22c. Fancy renovated, 18c.

NEW ORLEANS, La., May 11—Butter—Market firm; extras, 22; ladles, 15c; renovated, 18c.

Eggs—15c.

NEWARK, N. J., May 11—Butter-Market steady at 22c.

Eggs—Firm at 17c.

LIVERPOOL, May 11—Butter—Good United States steady, 75s.

Cheese—Steady; American finest, white and colored 68s. Stocks: Butter, 3,900 cwts.; cheese, 16,000 boxes.

CANTON, N. Y., May 9—Offered 190 boxes of large cheese; 1,125 Twins and 756 tubs of butter. Butter sold at 21c. Large cheese, 10⅞c; Twins at 11 13-16. Ruling price, 11¾c.

PHILADELPHIA, Pa., May 11—Butter steady, fair demand; extra western creamery, 22½c; do. near by prints, 23c.

Eggs—Firm, good demand; fresh near by, 16c at the mark; do western, 16¼@16½c; do south western, 16c; do southern, 15@15½c.

Cheese—Firm but quiet; old New York full creams, choice, small, 14¾@15c; do fair to good, 14@14½c; do choice, large, 14¾c; do fair to good, 14c; new New York full creams, best here 12¾c; fair to good, 12@12½.

ST. LOUIS, May 11—Butter—Slow; creamery, 16@21c; dairy, 13@16c.

Eggs—Higher, 13c fresh near by.

BALTIMORE MARKET.

BALTIMORE, May 7—Butter—Although there has been a decided increase in the general supply, there has been no accumulation of desirable stock. The decline in values has proven quite attractive to both the local and out-of-town buyers; hence, there has been a close clearance, from day to day, of all attractive offerings. Held creamery is meeting with little or no favor, and many instances large concessions have been made in order to effect sales. Good to choice imitation creamery meets prompt sale. All fresh sweet ladles find ready sale at steady prices. Roll—Owing to the approaching warm weather, we advise you to pack all rolls solid from now-on. Packing stock, when fresh and sweet, is in fair demand; old and rancid is slighted Blocks and prints continue in ample supply for the demand. The impression seems to prevail that prices have touched bottom for a while, and at the close the market presented a steady appearanecc

Creamery Separator, extras, 22@22½c; firsts, 20@21c; seconds, 18@20c. June Creamery, extras, 21@22c; firsts, 19@20c; seconds, 18c; Imitation Creamery, extras, 19@20c; firsts, 18c; seconds, 15@17c, Iowa & N. W. Ladle, extras, — firsts, 17c; seconds, 14@16c. Ohio & Indiana Ladle, extras, — firsts, 16@17c; seconds, 14@15c. Roll, Ohio, extras, — firsts, 13; seconds, 11@12c. Roll, W. Va., extras, — firsts, 13; seconds, 11@12c. Ohio Store packed, extras,— firsts, 13c; seconds, 12c. West Va. Store-packed, extras,—; firsts, 12@13c; seconds, 11@12c. Creamery blocks (2-lb.) extras, 23@24c; firsts, 21@22c; seconds, 20c; Creamery prints (½ lb) extras, 25c, firsts, 23@24c; seconds, 21@22c: Md. Va., & Penna. Prints, extras, 23c; firsts, 21@22c; seconds, 18@20c.

Eggs—The receipts continue fairly liberal; there has been so far a very good demand, both for local consumption and for the storage purposes: the Market today closes steady at 15 cents. We omit extra quotations on duck eggs as they will not command any more than hen eggs, and it is only a matter of a short time that they will not be wanted at all.

Cheese—The stock of old cheese is pretty well exhaused. Quotations given below with the exception of Cheddars, are for new cheese.

N. Y. State—Cheddars, fine, 15@15½c; choice, 14½@14¾c; fair, 13@13¾c; Flats, fine, 12@13c; choice, 11½@12c; fair, 10@11c; Small, fine, 13@13½c; choice, 12@12½c; fair, 11@11½; Ohio Flats, fine, 12½@13c; choice, 11½@12c; fair, 10@11c; O. Picnic, fine, 13@14c; choice, 12@12½c; fair, 11@11½c; Swiss Cheese, fine, 15c; choice, 12½@13½c; fair, 10@12c.

301 Exchange Place. G. M. LAMB & BRO.

NEW YORK MARKET

NEW YORK, May 9th.—Butter—Receipts for the week, 32,666 packages. Exports for the week, 35 packages.

Receipts were less than the trade anticipated and with increased demand, owing to the lower prices, stock was quick taken on arrival and at the close all grades table butter was wanted and prices are firm with every indication of a slight advance next week unless receipts are largely increased. Extra fresh creamery sold at 22c with small premium added for high scoring goods. Firsts sold at 21½ to 21¾c and under grades at 20 to 21c.

New York state dairy in demand and sells at 21c if fancy, and 18 to 20c for good lines. Ladle and all under grades Western selling quick and prices are unchanged. We quote:

Creamery, extra, 22c; medium, 21@21¾c; poor, 16@20c Dairy, extra, 21c; medium, 18@20c; poor, 15@17c. Ladle, creamery, extra, 18@20c: medium, 15@17c; poor, 12@14c.

Cheese—Receipts for the week, 21,259 boxes. Exports for the week, 12,199 boxes.

Increasing receipts, weak and declining prices were the features of the market. Exporters were free buyers of large cheese at 11¾ to 12¼c, and home trade took small sizes at a fraction more. We quote:

Full cream, old extra, 14¼@14½c; medium, 13@14c poor, 10@12½c. Full cream, new extra, 12@12¾c; medium, 11@11½c; poor, 10@10½c.

Eggs—Receipts for the week, 95,518 cases.

Favorable weather and good steady trading caused a strong market and all desirable parcels were taken at advanced prices. We quote:

New York & Penn., fancy, per doz., 17c; Northern & Western, fancy, per doz., 16½@17c; All Sections, poor to good, per doz., 13@16c.

...DAIRYING... PROSPERITY

The De Laval Cream Separators laid the foundation for the prosperity of modern dairying as an industry twenty years ago and

DAIRY PROSPERITY AND DE LAVAL SEPARATORS

have gone hand-in-hand ever since.

It is very much better to be prosperous and happy with a De Laval machine—factory or farm—than to make an uphill handicapped fight for success with a poor imitating machine.

A De Laval catalogue will help to make plain the practical difference between separators.

Buff Jersey's latest book on Farm Stock and Dairy Work is full of practical things for practical people. The Silo, how to build and fill; ensilage, its value; soil, crops, variety and how to grow. Swine, poultry and many other subjects ably treated. Send 25c for copy. Monmouth, Ill. 47-tf

Wanted—Experienced farm hand, able to milk well. Give age and wages wanted. ST. IVES PARK FARM, Mont Clare Station, Chicago, Ill. 41-tf

The Business Herd of Holstein-Friesian cows are being closed out at a great sacrifice, and if you want one or more officially tested, good business cows write at once and secure first choice. State just what you want and save time and correspondence. F G. JOHNSTON & CO., Sta. B, Columbus, O. 11-tf

Holstein-Friesian Bulls from one to fourteen months old at prices that will surprise you. O. J. GODFREY, Pennellville, N. Y. 11-tf

Wanted—Buyer for Victor combined churn No 2, 100-gal. cream vat, 60-gal. weigh can. All the above are in A No. 1 condition, used less than 1 year. We have no use for them and will price them low to a quick buyer. For full particulars inquire of E. T. SHAFFER, Polk City, Ia. 13-2

Dairy Cows For Sale—At a bargain. Administrators will close out one of the finest herds in the state, of thoroughbred Holsteins and Jerseys, and grades, noted for milk and butter qualities Your choice of fifty head. KEWANEE DAIRY FARM, Lock Box 115. Kewanee, Ill. 13-2

For Sale—At a bargain, a large dairy farm with up-to-date and first-class improvements. Large house, 2 large barns, large silo, fully equipped creamery plant and several outbuildings. Home market for all product at prices above top of Elgin market. Would sell either with or without stock. For particulars address C. O., care Hoard's Dairyman. 13-2

For Sale—Pure bred Guernsey bulls and grade heifers. Also Early Black Soy Beans at $2.00 per bushel. A. H. HINMAN, Neenah, Wis. 13-2

A Registered Guernsey Bull 15 months old for sale. A very fine animal. Inquire of J. S. HUNTER, Pickett, Wis. 12-tf

For Sale—Four young registered Guernsey cows, all fresh. J. E. STORY, Stanley, Wis. 11-tf

For Sale—Carload of grade Holstein springers C. BOTTMEA, Stock Yards, Indianapolis, Ind. 13-2

For Sale—Or will trade for a Jersey bull from 18 months to 2 years old, a Rider engine for pumping water. This engine is in first class condition and is sold for no fault. We have a steam pump and have no use for it. For full particulars write E. T. SHAFFER, Polk City, Ia. 13-2

Two choice young Guernsey bulls for sale. MRS. A. W. LEHMANN, Neosha, Dodge Co., Wis. 12-sp

Holsteins—Owing to pressure of other business I will sell 20 head of high class registered cows and heifers. All milking or heavy in calf. No culls. Prices very reasonable. Come and pick them out. Address HENRY C. GLISSMANN, Sta. B., Omaha, Neb. 14-2

Wanted—Position by cheese maker in up-to-date factory. Dairy School experience. Also can give reference. Address L. L. H., care of Hoard's Dairyman. 14-2

Do You Want—A Hay Fork Returner? Every farmer having a barn should have one. A hummer for agents. Circulars free. ROONEY RETURNER CO., Box D., Independence Iowa. 50-tf

Wanted—Single man on large dairy. Only good milkers need apply. F. W. ADAMSON, Lake Bluff, Ill. 4-tf.

Position Wanted—Experienced creamery manager wishes position as manager or butter maker in up-to-date creamery. Makes all by-products of milk. Taken one course at Cornell Dairy School. A No. 1 references. B. E., care Hoard's Dairyman. 11-tf

Wanted—Married man, competent to care for a dairy and work on small farm. A German with some help to milk preferred. House, garden, milk, etc. Addres BOX 46, Delafield, Wis. 13-2

Wanted—At once, expert condenser for partner. Prefer man able and willing to supply one half necessary capital. I have the raw milk at creamery and market for product in city. Address J. D. ROSZELL, 223 So. Mad., Peoria, Ill. 13-3

For Sale—De Laval "Dairy Steam-Turbine" separator, capacity 1000 lbs. per hour, used very little, in good condition. Going out of business. Address B. F. BRUNDRED, Oil City, Pa. 13-tf

Wanted—A first class butter-maker for town of 25,000 inhabitants in Mexico. Healthy climate. German-American speaking German preferred. State age, experience, and salary wanted. Should understand cheese-making and how to care for hogs. Will have house at factory and take meals free with superintendent. Address G. R., care of Hoard's Dairyman. 14-2

Wanted—Engineer and helper for butter-maker with some knowledge of butter making. Z. W. THOMAS, Ft. Dodge, Ia. 14-2

Wanted—A good sober and industrious man to take charge of a small dairy herd. Must be a good butter maker and good milker and be well recommended. State wages wanted in first letter. Address D. T. HILLMAN, Big Horn, Wyo. 14 3

Very Low Rates to California and Return—Via the North-Western Line. First-class round-trip tickets on sale May 3d and 12th to 18th, to Los Angeles and San Francisco. Favorable limits and stop over privileges and choice of routes. The overland limited, most luxurious train in the world, leaves Chicago daily 8:00 p. m. Less than three days en route. Drawing room and compartment sleeping cars, observation cars, dining cars, buffet-library cars, (barber and bath) electric lighted throughout. Three trains a day from Chicago to the coast through without change. Daily and personally conducted tourist car excursions to California, Washington or Oregon. For particulars apply to ticket agents Chicago & North-Western R'y. 8-7

To Colorado in 1903—The passenger department of the Chicago & North-Western Railway has issued a very interesting folder, giving information as to reduced rates and sleeping car service, with a short description of the various points of interest in Colorado usually visited by tourists, these excursion rates applying on account of the Christian Endeavor meeting to be held at Denver, July 9th to 13th. Send 2-centl stamp for copy, to W. B. KNISKERN, Passenger Traffic Manager Chicago. 9-6

Alfalfa for the Dairy.

[Paper prepared and read before Nebraska Dairymen's Association by J. H. C. BEEMER of York, Neb.]

In entering upon any line of work or business the object in view is the net returns that we may obtain from that work or business. It is in vain that the farmers organize clubs or institutes, it is in vain to expect to receive help from any legislature or corporation so long as he does not know that he must help himself through a sensible and practical management of his own occupation. As a farmer in Nebraska my idea from the first has been to depend mainly on stock, and not upon the marketing of grain, as a source of income, as we have worlds of summer feeds, and an abundance of native as well as cultivated grasses for summer pasture of the most nutritious kinds. But we always lacked suitable forage during our long and cold winters. Our cattle as a whole always do very well through the summer season, but, oh, how pitiful do the most of our Nebraska cattle look in the spring! Many of them lose about all of their summer gain during the winter season.

In my opinion the general raising of alfalfa, on the suitable soils, will satisfactorily settle the question of how best to provide an abundance of the very best nutritious winter food for our cattle, and keep them growing through the winter as well as through the summer. I do not intend to assert that alfalfa is adapted to, nor that it will succeed in, all sections of Nebraska. But certainly in each county there are localities of considerable extent where the soil conditions are such that the growth of it will be found to be a great success. The alfalfa root has been know to penetrate to the depth of more than thirty feet in search of moisture and plant food. It, therefore, may live and thrive where all other cultivated plants will wither and die.

The yield of alfalfa on suitable soil and under proper conditions has been with me more than twice as much dry forage per acre as I have been able to obtain from any other plant. On my farm in York county it is from sixty to seventy-five feet to water. In an average year the yield of alfalfa is from one to two tons per cutting, or from four to six tons per acre in the season.

The feeding qualities of alfalfa are unexcelled when the hay is cut at the right time and properly cured and housed or stacked. Cattle or any other stock prefer it to any other food. Our agricultural professors have been telling us that we must feed a balanced ration, as corn and other grains contain too much carbonaceous food and not enough protein. They advise us to buy and feed bran and linseed meal. Well, I have followed their advice and have bought and have fed tons of bran and linseed meal. But since I have raised alfalfa, I grow the protein, all I need of it, on my farm. A ton of good alfalfa hay contains, according to HOARD'S DAIRYMAN, 11 per cent of protein, or about the same as a ton of bran, for which I have been paying as much as $20 per ton. These professors may not figure it out that way, but after several years' experience, I do.

For the past eight or ten years I have been running a little experiment of my own, on my farm in York county. Most of my experiments have been along the line of testing the various grasses and forage plants and their adaptability to our locality and their feeding value for our stock. And I have found that alfalfa is the king of all forage plants. Last winter I fed a bunch of calves. The feeding period was two hundred days—from November 2, 1901 to May 20th, 1902. I fed them ten pounds of corn meal per head each day, feeding them twice a day. They had free access to alfalfa hay. I found at the end of the two hundred days that they had consumed thirty-six bushels of corn, and just about one ton of alfalfa hay per head. The average gain for the whole bunch was 450 lbs. per head. On May 20, I sold them at home for $5.40 per 100. When these calves were put into the feed lot on November 2, their average weight was 357 pounds. Figuring these 375 pounds at 4 cents per pound which was a fair price at that time, they paid me fifty cents for every bushel of corn they ate—what it was worth on the market—and $12.10 for every ton of alfalfa hay they ate. I was so well pleased with the result of the experiment that I want to raise more alfalfa and more calves to be fed on my farm.

The present winter I am feeding my last year's calf crop again, sixty head, and on account of our soft corn, which could not be shelled or ground, I have been feeding thus far the corn in the ear, cut in about one-inch pieces, ten pounds per head per day. I am feeding them twice a day. with free access to alfalfa. On December 11th, 1902, the whole bunch weighed 28,810 pounds. On January 17th, 1903, the bunch weighed 32,760 pounds. There was a gain in thirty-seven days of 3,950 pounds. Figuring their gain at 5 cents per pound, it makes $197.50. They ate, in these thirty-seven days, 300 bushels of corn and about eleven tons of alfalfa hay. The corn at market price was worth $75. This leaves $122.50 for the eleven tons of hay, or $11.13 per ton.

The yield of the alfalfa hay crop, last year, was at least six tons per acre, and six times $11.13 makes $66.78, the income per acre of alfalfa when fed to calves as I am doing. Surely this ought to be a good enough profit for anybody. This income from the hay crop is more than an average acre of lands sells for.

I will close by saying again that alfalfa is the king of all the forage crops or any other crops. Blessed is he who owns land where alfalfa grows, for the homes surrounded by fields of alfalfa have transformed the so-called "Nebraska desert" into a Garden of Eden.

If one-fourth of the cultivated area of Nebraska was sown to alfalfa, our people would enjoy an income from their lands far greater than that which could possibly be obtained from any other crop known to agriculture. It makes the contented cow give pails full of creamy milk, and the feeding steer will bawl for the alfalfa feed rack.

Mid-Summer Feed and the Silo.

Alfalfa in Minnesota.

ED. HOARD'S DAIRYMAN:—Although I have been a close student of the DAIRYMAN for some years past—in fact, longer than I have been dairying—I have never come to your columns to ask questions or offer suggestions, but the last few numbers of your most excellent paper have been so brim full of good things that I cannot resist the desire to voice my appreciation of them. Especially am I interested in the articles and questions bearing on the silo and silage.

After a number of years experience in feeding silage, I am fully persuaded that the silo will do more to reduce the cost and labor than any other method of storage known.

All well informed dairymen realize the necessity of providing a variety of soiling crops to supplement the short pasture of July and August. When the mid-summer sun and wind robs the pasture of much of its succulence and food value, we must provide our cows some additional ration if we would not see the milk

"ADVERTISEMENT".

POOR DOMINIE

Between the Devil and the Deep Sea.

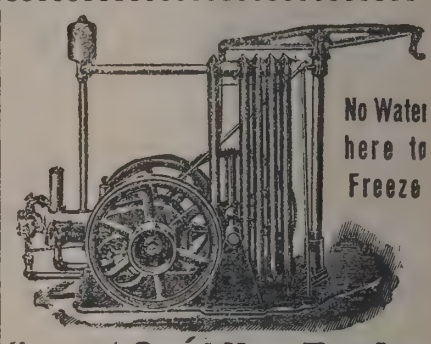
A clergyman of Gresham, Neb., who drank coffee for many years suffered from chronic insomnia and from terrific headaches when he quit coffee. He says: "I have been a very heavy user of coffee for so long and have seen its effects so clearly that there is now no doubt in my mind concerning its injurious effects upon the nervous system.

"While a coffee user I was unable to sleep for hours after retiring at night and on the other hand terrific headaches resulted if the regular hour for drinking coffee passed and I did not get it so I was in a miserable position.

"But I found a firm friend in Postum Cereal Coffee and from the very time that I adopted Postum all these evil effects vanished. I now enjoy sound sleep and improved appetite and a decidedly clearer complexion and I am convinced that better health and a longer life would be the result of its general use. I have a friend who has been a user of Postum for several years and the story of her recovery from neuralgia of the stomach simply by using Postum in place of coffee seems almost too wonderful to be true. Many times she was near Death's door and the doctors had frequently given her case up as hopeless but she was entirely healed by leaving off coffee and using Postum. It is a pleasure to say these good things about Postum." Name given by Postum Co., Battle Creek, Mich.

GASOLINE ENGINES

as power for the dairy have passed the experimental stage. Many dairymen now have them and all eventually must have them. The only questions to decide are the amount of power needed, and the most desirable make. With twenty-seven years of experience behind us, and a plant that has grown from 50 engines a year to 1500 a year capacity, we feel that we are equipped to build the best. There are other reasons why the "OTTO" is superior. We will tell them in this space from time to time. If in the meantime you need power, write us, mentioning this paper



THE OTTO GAS ENGINE WORKS, Philadelphia, Pa.

THOMPSON-LEWIS GASOLINE ENGINES

furnish the greatest possible power at the lowest possible cost in time, labor, fuel and money. They are so simple that anybody can run them without expert training or experience. Our Volume Governor gives uniform speed. Our Acme Mixer is the most positive and economical on the market. Our Hand Starting Lever starts engine with least effort. All bearings of Phosphor Bronze. Best material and workmanship throughout. Many sizes from 4 (actual) h. p. up. Best for all farm work—cutting and grinding feed, sawing wood, pumping water, separating cream, churning, etc. Send for our free catalog before you buy. It may save you time, money and annoyance.

J. THOMPSON & SONS MFG. CO., 113 BRIDGE ST., BELOIT, WIS.

If you want a..... Gasoline Engine that will be always ready to start, safe, reliable convenient, economical and durable, buy a FULLER & JOHNSON Frost Proof. No bother with water nor expense of broken cylinder, no waiting for wind or weather. All sizes, stationary and portable. Send for descriptive catalogue to the manufacturers.

FULLER & JOHNSON MFG. CO., Madison, Wis.

"COME in the evening or come in the morning, when you're looked for or come without warning"—

You'll always find your Tread Power ready for business. OF WHAT OTHER FARM MOTOR—Wind Steam or Gasoline—can this be said? A PERFECT GOVERNOR ensures absolutely even speed. Send for free catalogue.

St. Albans Foundry & Implement Co., St. Albans, Vt.

SHOO-FLY THE ANIMALS' FRIEND

Half cent's worth saves 3 quarts milk and much flesh. Kills every fly it strikes; keeps off the rest. Harmless to man or beast NO LICE in poultry house or any place it is sprayed. If your dealer does not keep it, send $1.00 for Improved Three Tube Sprayer and enough Shoo-Fly to protect 200 cows. Cash returned if cows are not protected.

product rapidly diminish and profits go with the wind.

Those who have had experience will not deny but that it is possible to maintain a fairly satisfactory flow of milk through July and August, if a liberal amount of soiling is provided the cows, and also they will not deny that the amount of labor required to prepare a soiling crop, cut it, haul it, and get it before the cows is a very considerable item.

Without doubt—and I speak from experience—the cheapest supplementary feed to the pasture is corn silage. A man can throw the amount of feed needed from a silo in less time than he can hitch up a team to cut it or haul it from the field, and no matter what the weather may be, or how pressing the field work, there can always be found time to attend to this very important chore.

In this age of push it is very important that we take advantage of every available means of economizing labor. "Time is money," and if we so plan and systematize our work that we can accomplish as much in twelve hours as in former years required fifteen, the much mooted question of hired help will be quickly disposed of.

But, I am digressing. In addition to providing us with mid-summer feed, is it not possible to employ the silo to a greater extent? Is it not entirely practical to keep our cows in a large yard until a crop of hay is stored, and then give them the use of the meadow. This method of course is not practical on farms where a meadow is used for years, but the number is fast increasing, who look upon the permanent pasture, and the sod bound meadow as a delusion and snare. Until turned to grass, feed plentifully of good silage, alfalfa or clover hay, and the necessary grain ration. In this way, that 20-, 30-, or 40-acre field that would otherwise be devoted to pasture can be made to produce a profitable market crop. If clover seed is sown with all small grain, fall feed will be abundant, and the fertility of our farms will be protected.

Having had the pleasure of meeting T. B. Terry, of Ohio, the article on page 242, of the current volume of the DAIRYMAN, written by that gentleman, is especially interesting to me.

Some years ago we became convinced, if we would derive satisfactory profit from our dairy, two things were absolutely necessary; viz: cheaper feed and better cows. Accordingly we began a search for a forage plant richer in protein than anything we were then growing.

Upon inquiry we found that in our county, at least two men were having good success with alfalfa. By good success, I mean they were obtaining about five tons of cured hay per acre, each season. This encouraged us to try it on our farms, so last year we sowed sixty-five pounds of seed on three acres of land. It was mowed once—about one ton to the acre—and at the present time seems very promising.

We shall sow 175 pounds of seed on seven acres of well fitted clover sod about May 15th, and instead of mowing once in the season for a crop of hay, shall mow sufficiently often that the growth may be left as a mulch.

We believe that the repeated pruning of the top will tend to strengthen the root.

If we can obtain four to five tons of alfalfa hay per acre and twelve to twenty tons of corn silage, then the problem of cheap feed is solved. Combine with these feeds clover hay and corn meal in the proper proportion and the ration is all that it need be. But important as it is to have good feed, this is of little avail, except that we have good cows to consume it.

Careful breeding and close selection, aided by the scale and the Babcock test, will surely tend to improve our dairies until they shall have reached a point far in advance of that which they occupy at the present time.

I may be classed an optimist by many, but I believe it entirely within reason, to set as a goal an average of 300 to 325 pounds of butter annually from each cow, and her food produced on approximately a single acre of ground.

When we have accomplished this, we will be entitled to the distinction of having caused at least two blades of grass to grow where before there was but one.

St. Charles, Minn. A. W. MOBRAY.

AN ACRE OF CORN
and its possibilities under the Silage system—being the theme of
"A BOOK ON SILAGE"
By Prof. F. W. WOLL
of the University of Wisconsin. Revised and up-to-date, neatly bound into a volume of 234 pages. It embraces full information from planting to feeding the crop, and includes working plans and specifications for building all silos. Also embraces:
I—Silage Crops. II—Silos.
III—Silage. IV—Feeding of Silage.
V—Comparison of Silage and other Feeds.
VI—The Silo in Modern Agriculture,
And illustrations and complete plans for round and rectangular silos, dairy barns, tables of compounded rations, etc. Mailed for 10c. coin or stamps.
SILVER MFG. CO.
Salem, Ohio.

No Matter What Its Company
may be, butter will be preserved through commission houses and markets as well as in the household, if it is wrapped in our
Pioneer Brand
Parchment Paper.
Outside smells and odors never penetrate through it, and it shuts in all the delicious flavor. Preserves butter better and longer than by any other means. If you make good butter you may get the name of so doing by letting us print your name, dairy or brand on every sheet. It never rubs off or discolors butter, and you can have no more effective advertisement. Parchment paper samples will quickly convince you of their value. Send for them. Sent free. Ask also for copy of our free book, entitled "Better Butter."

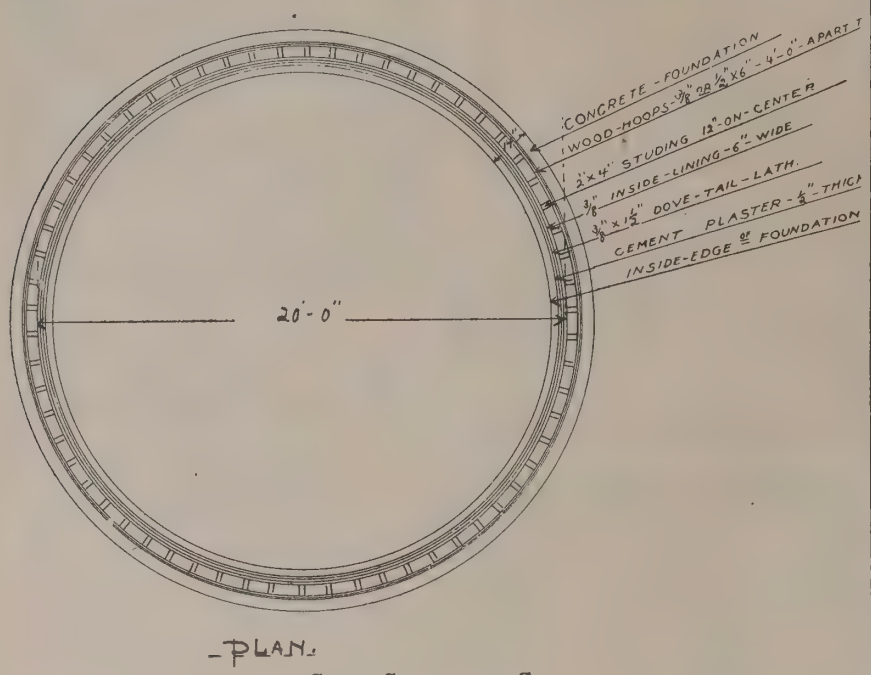
Silo Construction.

For the benefit of those of our readers who intend to build a cement lined silo, we publish plans and description of the form of silo used by H. B. Gurler, of De Kalb, Ill.:

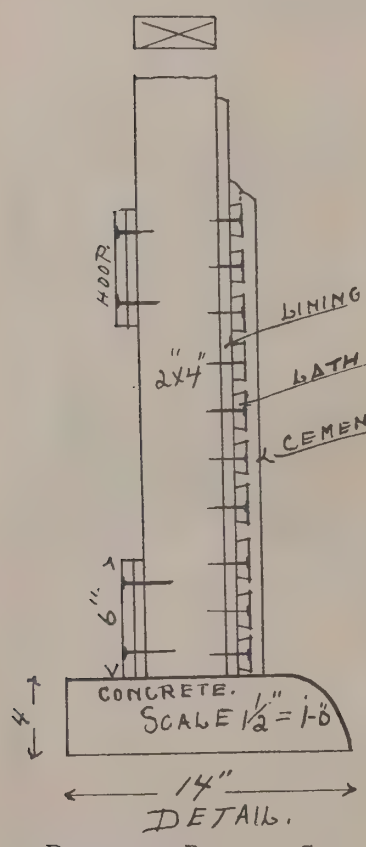
I built my first circular, cemented silos in 1897, building three that season; the next season I built one large circular one 38 feet in diameter. By the way, I shall not build any more so large, as when I open this one I am compelled to feed the whole herd in order to keep in advance of decay. This is no inconvenience so long as I have but the one of this size as I plan to open it when the whole herd (250) are being fed on silage. Since building my first cemented silos, my old wood ones went to the bad with decay and I put circular cemented ones in their places.

With five seasons' experience I am confident that the cemented silo is the most durable of any that I know anything of. I fully believe mine will last as long as I do—if I do not live past 100 years. The cement not only preserves the contents of the silo by its air tight wall but it also preserves the wood of which the silo is built, by preventing any moisture reaching it. In case the cement cracks, and I have had very little trouble in this line, the cracks we fill by using a wash made of cement, putting it on with a whitewash brush, just the same as one would stop the cracks in a leaky cistern.



We find that this makes the cement as good as new; in fact, we cannot tell that there have been cracks.

The cost is some greater than the wooden silo, I think. The one that I built in 1898, on which I put no roof, cost me 12½ cents per square foot of surface wall. To illustrate: A silo, 20 feet in diameter, is 63 feet in circumference, and if 38 feet high, it has 2,400 surface feet which, at 12½ cents per foot, would cost $300, and it would contain 250 tons. This does not include the cost of a roof which I believe to be a superfluity, after using the roofless one four years. My silos all have clay floors which I find all right, except when there is need of guarding against vermin.



The foundation may be of stone, brick, or grout, to the proper distance above the ground. I used 2×4 studding, 12 in. centres, but I think they might be put 15 or 16 in. centres as they simply hold the material together. The inside sheeting was secured by taking six inch fencing and having it resawed, making the material a little less than ½ inch thick. On this was put lath made from the same material, the lath being sawed with beveled edges so that when nailed onto the sheeting horizontally, the same as the sheeting is put on, we have a dovetailed joint between each lath which causes the cement to hold to the surface.

The patent grooved lath might be used if they could be sprung to the circle, but I found that I could not spring them to a less than 26 foot circle without their breaking. The first three circular silos that I built were placed in a row and inclosed with a frame building like a barn. These were not sheeted outside the studding. Not being certain that I had sufficient resistance to the lateral pressure in the inside sheeting lath and cement, I put wooden hoops outside the studding, using the same material that was used for sheeting the inside, putting it on double and breaking joints. I found I could get more resistance for the money in wooden hoops than I could in any form of iron hoops. For outside sheeting I believe it would be all right to use the same material that is used inside, in which case it acts as weather boarding and as hoops to resist the lateral pressure.

A Mr. Campbell, of my county, built last year a silo after my pattern and used the common lath by first putting lath onto the sheeting perpendicular on which he nailed the common lath horizontally. I believe this plan is all right though it will not give as solid a wall as when the lath are nailed to the sheeting, as we then secure a solid wall of lumber and cement one and a half inches thick. Use the best cement and be careful to secure a clean sand and you will have a good job if your mason understands his business, and you must be sure that he does before you employ him. For this work use one part cement and two parts of sand.

Cross Section of Silo.

Details of Base and Side, Showing Hoops, Lath and Cement.

A Small Corn Husker.

Ed. Hoard's Dairyman:—In reply to Fannie M. Smith's inquiry about small corn huskers, in Hoard's Dairyman of May 1, 1903, will say that if she will write to Alfonso Walrath, Fort Plain, Montgomery Co., N. Y., she will find just the thing—a small corn husker easily run by a two horse power. L. S. St. J.

COOPER SALE MAY 30
AT COOPERSBURG, PA.

A PLEASED BUYER IS THE BEST ADVERTISEMENT.

The Cattle sold at our May, 1902, Auction Sale have given universal satisfaction. My most sanguine expectations have been more than realized. How could it be otherwise? Individually they were strictly First-Class.

BEST OF ALL, they were bred on both dam and sire's side from animals that have made the Island cattle so famous—the blood that wins at the churn and in the show-ring.

☞Catalogues ready for distribution April 20th. Owing to great cost publishing same, they will only be sent on application. Address T. S. COOPER, "Linden Grove," Coopersburg, Pa.

AT DAIRYMEN PRICE One Grandson of Brown Bessie fit for service at Dairymen price on account of being broken color. Sire **Recorder**, the only living son of **Brown Bessie**. Dam **Bosnia**, 87508, record 20 lbs. 2 oz., a daughter of **Diploma**. Sire and dam solid color. Combines the blood of the winners close up.
H C. TAYLOR, Orfordville, Wis.

Short Weights Make Short Purses

"I cannot **afford** to be without a scale any longer," wrote an **Osgood buyer. Can you?** Our prices and terms are very reasonable for high grade scales. Free Catalogue. **Osgood Scale Co., 91 Central St., Binghamton, N.Y.**

Some Comments on a Holstein Record.

The Food not Disproportionate to the Reported Yield of Butter Fat.

ED. HOARD'S DAIRYMAN:—I see in the official records of Holstein-Friesians in this week's issue, that of May Hartog Pauline DeKol it states that the food consumed was as follows:

Ensilage	56	lbs.
Hay	99	"
Turnips	315	"
Hominy chop	51.5	"
Gluten feed	48	"
Oats	24.5	"
Bran	45.3	"
Oil meal	22.7	"

Will you kindly give the amount of dry matter, protein, carbohydrates and ether extract in a table, and compare a daily average of it with a daily balanced ration? S. C. BROWN.

Clifford, N. Y.

We are very much indebted to Mr. Brown for calling our attention to this specific record of May Hartog Pauline DeKol, as it is more than likely that, under the pressure of other duties, it would have escaped the attention which it really deserves. As requested, we set out in tabular form below the amount of dry matter and digestible nutrients reported to have been fed this cow during a period of seven days:

	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
56 lbs. lbs. silage	14.78	.73	7.84	.34
99 lbs. hay	78.12	1.62	39.06	1.26
315 lbs. turnips	29.92	3.15	22.68	.63
51¼ lbs. hominy chop	45.78	4.43	33.37	3.45
48 lbs. gluten feed	43.20	11.18	24.33	1.30
24½ lbs. oats	21.80	2.25	11.59	1.03
45.3 lbs. bran	39.91	5.71	17.48	1.36
22.7 lbs. oil meal	20.61	6.65	7.42	1.59
Total for 7 days	294.12	35.72	163.77	11.01
Average per day	42.02	5.10	23.39	1.57

It seems almost incredible that a cow could be induced to eat such an amount of food, and still more incredible, that if eaten, it could be digested and assimilated. We are all accustomed to think that thirty pounds of dry matter containing two and one-half pounds of digestible protein, sixteen pounds of digestible carbohydrates and one pound of digestible fat is about the limit. Reducing the fat to its equivalent carbohydrates will give twenty-one pounds of digestible nutrients in such a ration, whereas, this Holstein cow consumed thirty-two pounds of digestible nutrients, or fifty per cent more than we have been accustomed to consider the limit.

But there is an important element in this record, not mentioned by our correspondent, and that is, that during the seven days when she was eating this larger amount of feed, this cow produced 23.417 pounds of butter fat—over three pounds per day, which is nearly twice as much as we should expect from a cow receiving our maximum ration as above. Stated in another way, this cow used only nine pounds of digestible matter out of which to make one pound of butter fat, whereas, it is an extra good cow that does not use at least thirteen to fourteen pounds of digestible matter for this purpose.

Taking the yield into consideration, the amount of feed eaten is not only reasonable but remarkably moderate.

These figures bring into bold relief the fact, which we have often mentioned but which receive too little consideration, and that is, that the profit from the milk product of a cow comes wholly from the amount of feed consumed in excess of that demanded for maintenance. It cost no more feed to maintain this cow than it would to have maintained any other cow of same weight, yielding perhaps less than a quarter as much. Assuming, as not far out of the way, that it required 11 lbs. of digestible nutrients daily to maintain May Hartog Pauline De Kol, there remained 19 lbs. applicable to the production of milk. In other words, only about 36 per cent of what she ate was used for mainteinance and 64 per cent was devoted to profit, whereas, as we ordinarily feed cows, these figures are at least reversed, and more frequently than otherwise the food of mainteinance is 75 per cent.

Shepherd's Aerator

is most simple, most effective, least trouble. While you go on milking millions of air globules from the charged tank are passing up through the milk, driving out all animal heat and foreign odors. Works in shipping can. No other vessel to clean. **King among Aerators.** All dairymen prize it. Write for descriptive circular.

Wm. O. Jackson & Sons, South Bend, Ind.

Renting Out Cows.

W. B. C. asks through the *Ohio Farmer* what would be a fair rent for a herd of grade Jersey milch cows, all to be fresh soon, with a test of 4.8 per cent when fresh; remaining time, 5 per cent butter fat. Wants to keep the cows till fresh and veal the calves, then turn them over to a young farmer who feeds, pastures and cares for them for one year. The milk goes to a creamery that paid last year 18 to 29 cents for butter. What portion of the money should he receive for the use of his cows, all in good condition?

This is a singular phase of dairy work and would receive as many answers as there were persons asked. In replying to this query let the writer review some facts coming under his observation among 30 dairymen who were patrons of the same creamery. It cost them $28 on an average to keep a cow, with an average of a little over $14 net profit. The highest got $32.86 net profit and the lowest fellow lost $9.12 with a cost of $40 per cow.

Figuring from the highest gross receipts for the year, $60.56, with 5,544 lbs. of milk and 80 per cent skim milk returnable, worth 20 cents per 100 lbs. for young calves and pigs, or $8.87, then each ton is worth $2 in fertility, or better than 2 tons per cow, worth $4, and $3 after fed, to return to the soil. This makes a total of $72.43, the output of the best herd of the 30 herds.

The average of these 30 dairies in milk was 4,200 lbs. If W. B. C.'s cows will do this well with 4.8 per cent fat test, there will be 235 lbs. of butter to sell at creamery. A range of 18 to 29 cents will average 23 cents for the year, or $54, gross receipts to divide, or $27 net proceeds in the hands of the renter. To this $54 plus $6.72 plus $2.50 for skim milk at 20 cents per 100, the renter has $63.22 besides the 70 per cent of the fertility of the feed consumed in producing milk. The latter is possibly worth most of the care of the cow, as a cow is estimated to leave close to $17 worth of manure per year, if carefully saved.

Either at the beginning or the end of the year the owner would have a crop of calves to add to his credit, worth $5 each. I should want the renter to indemnify me to return the same number of cows and as good, aside from one year's wear out of them, and give me 10 per cent of the gross income from the creamery. This is an untried theory because it is out of the usual way, and I only give these figures by way of starting other opinions.

The question of renting dairy farms is one of the perplexing problems that is making not a few dairymen spend sleepless nights. To find a careful man who can be trusted to take hold of a good and carefully selected herd of cows, and go right along with them without interruption, is a difficult matter. We believe it to be difficult for an absolute stranger to step in and take up the work and pursue it properly without some little jar to the regular routine.

It doubtless would be better that the applicant spend one year as an employe of such a dairy, and if at the end of the year all things went right, pleasant and profitable, then it would certainly be safe to rent out on the thirds or halves as the case might be.

A letter from a prominent dairyman asks a question along that line. He says: "I have a good man with me by the year, and would like to release myself from the constant confinement of the dairy and the farm. What would you advise? Well, just what we note above is what we would advise, and as this dairyman is in a position to know what his man can do, and understands his methods and tactics, he can take him in or reject his proffer. No owner of cows can afford to release the control of his herd or his business, until the man who rents has been well tried and tested. A renter who means business and wants to make a living and some money, will not object to be "run," as some would term it. If he persisted in "taking the reins" it would be safe in dropping that fellow.

This applies more closely to strangers than acquaintances. Some very good men have been secured through advertising, but cannot be relied on very often. I would consider it a much safer plan to see and know my man at the farm. Some fellows are good letter writers, and too often the scrawl will be overlooked. I bring to mind one case where a man highly educated wrote me a long, well written letter, full of high sounding phrases. He was in need of a gardener and wanted me to recommend a man. I sent him a nice, moral, intelligent man. The former turned out to be a very highly educated man, but immoral, drinking and corrupt, with whom no self-respecting man would stay. I would certainly know my man, where he came from, what the circumstances were that put him in the market for renting, etc.

I can cite two cases. A neighbor who had lived 4 years adjoining our farm, was a renter. His landlord died and the farm was sold. When it was known that he was in need of a farm to rent, a dozen landlords fell over each other to get him. Another who couldn't stay where he was, hunted over parts of two counties before he found a farm, and then neither he nor his landlord were suited.

Dairy work is hard, confining labor, and the tenant who does it should have a good chance. I believe that chance should come to him in a way that would encourage him. For the tenant who furnishes team and farm outfit, I should have the dairy furnished to start him, with the understanding that the increase from the herd should eventually form a partnership herd—landlord and tenant sharing equally in the proceeds of the farm, each furnishing half of the seed, the tenant doing all the work and furnishing half of purchased feed and all expense of repairs, half of fertilizers, transportation, etc.

If the tenant be a "thirds" man he should have team and farm outfit furnished along with a herd and dairy outfit for whatever character of dairy work he may engage in, a house, garden and truck patch free, and in return he should engage to do all work pertaining to the farm and dairy and give the landlord two-thirds of the proceeds in either products or cash as the landlord may demand.

I am not writing altogether from the landlord's side, as I have been a tenant and worked this very farm on the shares, and think I know just what is right as between capital and labor. I think the tenant should have every consideration shown him.

There is one thing that demands forcible mention. A landlord has the right to demand of his tenant his constant attention to business, to see that work is done properly and in season. In one sense a tenant is an employe who is expected to put his labor against capital, to make that capital pay the highest dividend, from which said tenant expects to reap his reward. If by neglect of duty that tenant robs his employer out of a good return, he is surely a bad investment and deserves to be discharged. Sometimes landlords fail to do their part in furnishing teams, outfit and good seed and utterly fail to encourage the tenant, who starves out and quits if he has money enought to get away. Landlordism and tenantism should be brought up to a higher standard than it has been in the past. Both factors have great need to study the situation and conditions that surround them as men of business, and step above the little things that so often

THE
Iowa Dairy Separator.
AN UP-TO-DATE MACHINE
REPLETE WITH PRACTICAL IDEAS
It is built in the following sizes:
250, 350, 450, 600, 750 POUNDS PER HOUR
Our 750 pound per hour machine is a practical Hand Separator. It is as easily run as most separators of 450 pounds and 500 pounds capacity.

DAIRYMEN'S SUPPLY CO, Phil'adelphia, Pa.

Reid's Hand SEPARATOR

The "best" separator is that one which does its work most thoroughly and easily, that is built of strongest material, and that is most easily washed and kept in order.
First cost is a great point with a buyer, but ease of running, perfection of skimming and simplicity in washing are even greater considerations.
The **Reid Hand Separator** has but a single cylinder inside the bowl, and skims as closely as one-hundredth of one per cent. Indeed, some tests indicate "not a trace" of fat in the skim milk.
The Reid is perfectly planned and strongly built, and it literally "runs like a watch."
As to our guarantee of excellence, we make the strongest statement that can be expressed in words: **Money back (less freight) if the buyer is not satisfied.**
There is a new (free) booklet about the Reid Hand Separator.
Sizes run from 150 lbs. to 500 lbs. per hour.

make trouble. A written contract is all right, but honor, high minded integrity and industry, with a love for right doing is worth a hundred iron clad agreement.—GEO. E. SCOTT *in Ohio Farmer.*

Does it Pay to Feed Cattle at the Present Prices of Grain?

ED. HOARD'S DAIRYMAN:—We hear so much said by a class of people, not necessarily restricted to farmers, who sit around a grocery store on boxes and barrels and tell you all about your business and other people's business, how they should do, what they should eat, wear, etc., where to go, when to go and where not to go, and, in fact, do the business for the whole community, when the facts are shown they have been drudging along from 20 to 40 years in the same old rut, with the only ambition of making a living and hardly that, and when a person who is trying to work along a different line, if he paid any attention to what was said, would get discouraged and never try, but having a little determination and from studying the ways of breeders and advanced dairymen from such papers as HOARD'S DAIRYMAN, I was led to believe that caring for cattle in a way that they should be taken care of, would pay a much better per cent than by starving and neglecting one's stock to save the cost of feed.

While I am a very ardent Guernsey man, I have all the different milk strains of cattle to look after on our farms, and I think that any breed of the dairy type cattle that best suits your taste and circumstances, can be made to pay a larger revenue if more attention was paid to the milking strains than to go by the straight back, heavy cows without any regard to ancestry or milking points. Is it not a fact that too many farmers buy cows for the going price, giving more preference to size and a large calf to sell for veal than anything else? Why is it that they pay so little attention to milking records when they depend almost entirely on the amount of milk which they deliver at the cheese factory to make their living?

It is a fact that one can start at Belmont, N. Y., follow the main road to Hornellsville, a distance of about 25 miles, which is entirely a dairy section, and if the cows that did not give 5,000 lbs. milk per year were thrown out, there would be very few left.

And still the cow that does not give 5,000 pounds of milk per year, runs her owner in debt every year he keeps her, for she will certainly not pay for her keeping, figuring what you can sell the produce she consumes during the winter, at the market value, time and labor caring for said stock thrown in.

Now, if the said people are contented with their way of doing business, depriving themselves of all luxuries, and sometimes of the necessaries of life that go to make up this little life of ours, which is made a success or a failure by one's own efforts, they are entirely welcome to their opinions. I think it is better, instead of having cows look just so in regard to size, spots, color, straight backs and all other nonsense that does not conform to the milk in the pail, to pay more attention to the milking points, if it is milk you are after, for the cow that gives the largest quantity and quality is the best and most profitable cow in every instance, where milk is the main product.

In my barn the cows have all feed weighed and charged to them; milk weighed every milking, and cow given credit for the same; milk tested every month, thereby finding out my best cows; I have fed well all winter with high-priced feed; have not a cow in the barn which has not paid her way all winter. Butter sold on contract for 25 cents the year around. No cows died, all look well, feel well; no disease, and all of them pay for their keeping and most of them give good profit besides.

Daisy, a 3-year-old heifer dropped fine heifer calf, Feb. 16th; milk record for March, 1,097 lbs.; test, 4.9 per cent; No. lbs. butter fat 53.75 at 25 cents per pound $13.44. She was fed 12 lbs. grain, per day, or for the month 372 lbs. at $1.20 per hundred is $4.46; 20 lbs. hay per day at $10 per ton is $3.10; total $7.56, leaving balance in favor of heifer of $5.88 not allowing anything for skim milk, which was fed to hogs that on the 27th day of January weighed on an average of 31½ pounds each, and on May 1st weight, 150 pounds, so you can figure what skim milk is worth per hundred. Darling of the Highlands 13373, 3-year-old-heifer, dropped calf Jan. 30; milk record February, 926½ pounds; test 5%; March 1060 pounds, test 4.8%; April, 941 pounds, test 5%; total amount butter fat in three months, 144.26 pounds. The 22 months-old heifer, Madge of the Highlands, has also made a nice showing. She is a very handsome, dairy type heifer, has taken 1st premium everywhere she has been shown, milked as high as 24 lbs. 5% milk per day in March.

So I might go on and enumerate all through my herd. These facts and figures convince me that it is good policy to have good cattle and then take good care of them and get paid for your feed, time and trouble.

Holstein-Friesian Association Meeting.

The Eighteenth Annual Meeting of the Holstein-Friesian Association of America will be held at the Yates Hotel, Syracuse, New York, on Wednesday, June 3, 1903, at 10 o'clock a. m., for the election of officers and the transaction of any other business which may leagally come before it.

The following propositions will be offered:

By Mr. Geo. Rice, to reduce the registration fee on bulls.

To appropriate money and authorize the Board of Officers to offer to award special prizes of duplicate premiums, where won by animals recorded in this herd-book, in public competitions for yields of milk or butter or both, and for quality of butter, at such exhibitions as the Board of Officers may select; and to authorize special prizes at fairs where no competitive tests are held, or to establish competitive test under such conditions as they may deem best; and to offer prizes for the exhibition of cattle at such fairs and expositions as may be deemed best.

To appropriate money therefor, and to authorize the Board of Officers to continue the system of prizes for officially authenticated butter records and for economic tests substantially as last year.

To appropriate money therefor, and to authorize the Literary Committee to carry on such work as it may deem proper for the interests of the breed.

COMMON SENSE Calf Feeder

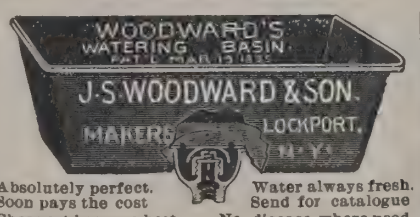
awarded Gold Medal at Pan-American Exposition. The only Feeder adopted by experiment stations. It is the kind others try to imitate. Easiest to operate and clean.

Most Durable, Simple, Economical, Scientific and Practical.

Do not be deceived by imitators. Shams are never imitated. **More Common Sense Feeders are in use than all others combined.** Over 50,000 in use. No valves to get clogged or foul. Nipples reinforced and cannot collapse. The calf feeder is a perfect weaner. A substitute for nature.

Extra gain on one calf pays for two feeders.

Best Feeder Made.
Michigan State Board of Health:—I tried every Calf Feeder I could find, but liked yours best.



Worth $10.00.
George S. Bement, Victor, N. Y.:—I am very much pleased with the Feeder and would not be without it for $10. No trouble, no damning, no milk on your clothes, no trouble to teach the calves to take hold of it, no sucking the cows, and the best of all is that when they get about eight weeks old they don't stop for the nipple but just drink out of the pail.

The Principle is Correct.
Purdue University Agricultural Experiment Station of Indiana, LaFayette, Ind.:—We have been using the Feeder to some extent and it is in constant use at this time and we believe it to be very satisfactory in its work. The principle of **Your Feeder,** I believe to be the correct one. C. PLUMB, Director.

Advise Stock Raisers to use it.
Maryland Veterinary Hospital:—I am very much pleased with the Feeder and would advise stock raisers not to be without one.

Price $1.50 including two nipples, sent postpaid for $1.75. We guarantee satisfaction, but if you are in doubt about its value we will send one on approval for 50c to cover postage, remainder to be paid if satisfactory. **Be Sure** and send for our twenty-two reasons why you should use a feeder. It's free. Sold by one dealer in a town.

CHICAGO HOUSE WRECKING CO. WEST 35TH AND IRON STREETS, CHICAGO.

The McGeoch Sale.

ED. HOARD'S DAIRYMAN:—On Wednesday May 6th the sale of Holstein-Friesian cattle from the McGeoch herd was held at Red Brae, the old McGeoch homestead, just out of the city of Milwaukee.

The cattle were an exceedingly attractive lot barring a few quite old cows. Some few animals that were catalogued, were not sold and others were substituted, sixty seven in all passing under the hammer and the average price received was $213.00, this being the highest average that has been reached at a Holstein sale in the past fifteen years.

Among those present were Mr. W. J. Gillett, of Wisconsin and Mr. F. L. Houghton, of Vermont, President and Secretary of the Holstein-Friesian Ass'n.; W. A. Matteson and Dr. Dewing of Utica, N. Y.; Mr. H. A. Moyer, of Syracuse, N. Y.; Mr. J. H. D. Whitcomb, of Littleton, Mass.; Mr. Albert Fields, of Maryland; Mr. Jas. A. Graham, of Patterson, N. J.; Mr. R. M. Hotaling and Mr. Chas. D. Pierce of San Francisco. Cal. In addition to these, about all of the prominent breeders of the middle West were in attendance.

The greatest enthusiasm prevailed throughout the sale and at times the bidding was so rapid that it was hard for the auctioneer to locate it.

The center of attraction centered in the great breeding bull, Gem Pietertje Hengerveld Paul DeKol, and his daughters, the bull himself being knocked down to Mr. F. A. W. Kieckhefer of Milwaukee, at $900.00, while Messrs. Frank B. and E. J. Fargo of Lake Mills, secured the most of his daughters, so that they will be returned to within a mile of where they were bred and born.

The heifer, Duchess Ormsby 2d Hengerveld DeKol, a daughter of the above bull, proved to be the highest priced animal sold. The first bid was made by Mr. Carpenter, of Michigan, at $500.00, this was jumped at $100.00 bids until $1,200.00 was reached. Here the bidding hung for a moment, then went on at raises of $25.00 until $1,400.00 was reached, where she was knocked down to the Messrs. Fargo, at what proved to be the longest price of the day.

Many other Wisconsin breeders were among the best bidders at the sale, especially noticeable among these being Messrs. S. B. Jones & Son and W. H. Jones, of Watertown, Mr. F. A. W. Kieckhefer, of Milwaukee, and Mr. L. T. Gay, of Madison, while Dr. Rounseville and Mr. Geo. Hooper, of Milladore, although they managed to secure only two head, were among the most persistent bidders.

Take it all in all, the sale was a decided success, and it is with much pleasure that we are able to state that Wisconsin bred cattle have sold at auction and reached the highest average that has been made for years, for this breed of cattle. H.

An Iowa Herd Record and Skim Milk Value.

ED. HOARD'S DAIRYMAN:—In renewing my subscription, I will send the results of my herd of Holstein cows, 16 head. Three of them were 2 years old, 4 were 3 years old.

FROM JAN. 1ST TO DEC. 31ST, 1902.

Pounds of milk produced	109,997
Pounds of butter fat sold, 3,944 91-100	$876.07
Pounds of butter fat used at home, 251 88-100	56.71
Pounds of whole milk sold, 664	5.97
Skimmed milk at 25c per 100 97,652	244.13
Total	$1,182.88

Seven years last Dec., I commenced dairying. My first month's milk check was 90 cents; last December over $90. I am now past 53 years of age. I commenced taking HOARD'S DAIRYMAN about four years ago, and I learned more from it in three months about the feeding and management of cows than I ever knew before, so whatever success I have I owe it to HOARD'S DAIRYMAN, and it is hard to get farmers to see their need of it. I use a separator. Nine of these cows are grades, 6 of them full bloods, 1 a Short-horn. She is doing duty for another man now. To satisfy myself of the value of the separator milk for pig feeding, I bought 10 shoats the 18th of February. They weighed 1,330 pounds. I paid $6.75 per 100 pounds. I sold them at the end of 62 days feeding. They weighed 2,610 pounds, or a gain of 128 pounds per head. I sold for $6.80. I fed them 62½ bushels of corn and 7,000 pounds of milk; allowing 10½ pounds per bushel of corn would leave nearly 9 pounds per 100 for milk, or in other words, 71 cents per bushel for corn and 60 cents per 100 for milk. R. R.

Conway, Iowa.

Spreading vs. Piling Manure on Land.

ED. HOARD'S DAIRYMAN:—May I call your attention to an experiment being conducted by Prof. W. P. Brooks of the Hatch Experiment Station, Amherst, Mass., and called to my notice by a letter that appeared in the DAIRYMAN of March 13th?

Prof. Brooks took a field that had been divided into five plots. On the north half of each plot he spread manure in the winter and at the same time upon the south half of each plot he piled an equal amount of manure to be spread in the spring. In every case there was an increase in yield on the half plots where the manure was piled, averaging 13.7% in 1900 and 44.1% in 1901. The total yield of the field was much smaller the second year, due probably to an unfavorable season.

While he cautions against attaching undue importance to these results, Prof. Brooks says (Hatch Exp. Sta. Report, Jan. 1902, p. 51), "This experiment will be continued, but * * * the results certainly indicate that there is grave reason to doubt whether application of fresh manure during the winter and allowing it

THE "1900" FAMILY WASHER FREE.

Greatest Invention of the Age. Labor and Expense of Washing Clothes Cut in Two.

No More Stooping, Rubbing or Boiling of Clothes.

Every Household Needs One.

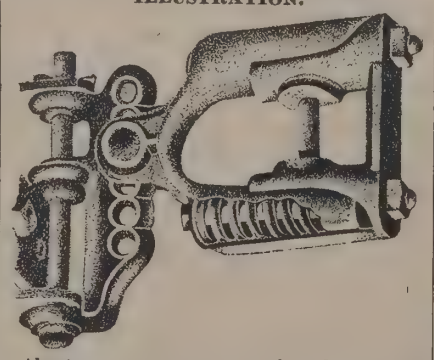
THE "1900" BALL-BEARING FAMILY WASHER SENT FREE

to anyone answering this advertisement, without deposit or advance payment of any kind, freight paid, on 30 days trial. The 1900 Ball-Bearing Washer is unquestionably the greatest labor saving machine ever invented for family use. Entirely new principle. It is simplicity itself. There are no wheels, paddles, rockers, cranks or complicated machinery. It revolves on bicycle ball-bearings, making it by far the easiest running washer on the market. No strength required, a child can operate it.

No more stooping, rubbing, boiling of clothes. Hot water and soap all that is needed. It will wash large quantities of clothes (no matter how soiled) perfectly clean in 6 minutes. Impossible to injure the most delicate fabrics.

AN ENTHUSIASTIC ADMIRER.

CHICAGO, July 17, 1901.
Nineteen Hundred Washer Co.,
Binghamton, N. Y.



I started to wash with your "1900 Ball-Bearing Washer" at 10:30 a. m. and in half an hour the contents of two machines were washed clean, rinsed and hung on the line. A neighbor called as I started to wash my little boy's waists (which were terribly dirty), and in ten minutes I wrung them out and we were very much surprised to see that there was not a spot left. On Monday we did a big wash of fifteen machinefuls of clothes in four hours. The lady living upstairs saw that we turned out so much work in such a short time that she asked us to loan her the washer for Tuesday, which we did. She has a Western Washer, which she could never use, as it took a man to turn the machine. The "1900" is by far the best machine I ever saw. It works so easily that my little boy can run it. You are at liberty to refer anybody to me for further proof.

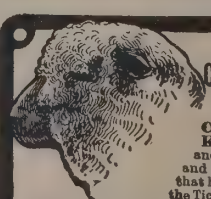
ILLUSTRATION.

About a year ago we were pleased to call the attention of our patrons to the merits of a Spring Clevis which has been advertised in our columns almost constantly for two years or more. The makers—David Bradley Mfg. Co.,—tell us that orders for them are steadily increasing in number, and that the sale of one is sure to bring other orders from the locality to which it is sent. It is a great boon to farmers who have land in which a plow is liable to strike stumps, roots or other obstructions, as it contains a large amount of stored-up elasticity, which prevents or absorbs the jar, that would, without it, be spent upon the team, harness and plow. At points where dealers do not carry them, the manufacturers will send them, charges prepaid, for $1.25, cash with the order. You might save twice that amount in broken plows and harness in one season, besides it saves the team many a jolt and jerk and finds them less tired at the close of the day's work. Descriptive circulars to any one who will ask for them by addressing David Bradley Mfg. Co., Bradley, Ills.

Cherry's Perfected Barn Equipments.
Operates on Curves and Switches. Manure Carrier, Feed Carrier, Grain Elevator and Track. Barn Door Fixtures and Track. Hay Tools.

Send for Illustrated Catalogue and Price List to
D. B. CHERRY & CO., Knoxville, Iowa.



THE DREW ELEVATED CARRIER
is the cheapest and most practical device for taking away manure from stables, carrying ensilage, feed, grain, etc., etc. No trouble to put them up; no trick to work them; leaves barn yard free from posts; dump in yard or on wagon; turns curves and switches. An inexpensive money saver. Write for illustrated catalogue and full particulars.
DREW ELEVATED CARRIER COMPANY, : : : WATERLOO, WIS.

USE GOODWIN'S FLY KILLER this season on your cows and horses and be rid of the fly pest. Cows give 25 per cent. more milk and horses are relieved. Gallon 75c, 5 gallons $3.00, 10 gallons $5.50. Sprayers 50c, or send $1.00 for sprayer and enough Fly Killer to protect 150 cows.

WEST DISINFECTING CO., Inc.,
8 East 59th Street, New York.

to lie upon the surface till spring, is wise."

I have spread manure upon this farm winter after winter, for years. The farm has grown steadily richer, and I might say therefore the winter application of manure is justified. But may not the large amount of manure used have made the farm rich in spite of winter spreading, not because of it? C, I. B.

Blue Mounds, Wis.

CONCERNING OUR ADVERTISERS.

"Creston, Ill., January, 1903.
We have used quite a bit of your Zenoleum and we are well pleased with it as a disinfectant.
Yours truly, STANLEY R. PIERCE.

A WIDE SWATH

And a clean one is cut by the "Milwaukee" Mower. It is a simple, substantial, chain driven machine—no lost motion or delay in doing its work. It cuts from the word "go," and keeps on cutting as quickly and as long as the wheels revolve. It adapts itself to smooth prairie meadows or rocky and rolling hilly stretches. Their local agents will cheerfully impart further information concerning this sturdy machine, or furnish catalog. This machine is manufactured by the Milwaukee Division, International Harvester Co., Milwaukee, Wis.

There are land companies and land companies, but when any land company has shown that the land it handles is of a high grade and that the men who handle the business are thoroughly reliable, that company is a good one to deal with. The Polk County Land and Loan Company has been in business in Crookston for a year and the people for whom they have handled land, and the incomers and settlers to whom they have sold land are satisfied with the deals that have been made. This is the kind of a testimonial that counts. Where business is conducted with dispatch, with ability and with honesty, men like to deal, and this is why the Polk County Land and Loan Company's business is increasing as it is. They have for sale as fine a lot of land—improved or unimproved—as there is to be found and the prices are reasonable. The Polk County Land Company of Crookston, Minn., handle very largely the Red River Valley lands and any buyer of farm lands is certainly making a mistake that does not try to know the propositions they offer. Look up their ad in Hoard's Dairyman and write.

HE WAS PLEASED WITH THEM.

New Preston, Ct., May 1, 1903. Mr. J. S. Biesecker, 59 Murray St., N. Y. Dear Sir:—The 40 quart milk cans I ordered of you came yesterday. I am more than pleased with them. They seem to be so strongly put together, and so nicely stamped and marked, I shall surely order of you again when I need more cans. I shall give you and your cans a good word whenever I can. Yours truly, E. E. MEEKER.

A GOOD DIP.

There is no question about the advisability of dipping or spraying stock and poultry. A germicide and insecticide that will relieve cattle, horses, sheep, swine and fowls of the numerous pests that make their life a burden and destroy their useful ness and value to the owner is a recognized necessity for every grower of stock for profit. Among the many dips and stock remedies that are offered Chloro-Naptholeum has easily secured a leading position, by reason of the severity and thoroughness of the tests to which it has been repeatedly put by both the most extensive breeders themselves and the various experiment stations. It has the merit of safety as well as efficiency, being harmless to stock and handlers, and also is convenient in use, requiring no heating or other preparations, being a concentration of extra strength, diluted by the uses with many times its bulk of water. This makes it more economicial in use than the cheaper dips—dips that are cheaper to buy per gallon, but lacking in efficiency and in the end more expensive. The West Disinfecting Co., 26 East 59th St., New York, the makers of Chloro-Naptholeum, desire to place their book and unbiased testimonials from users in the hands of our readers who are interested. A postal card requesting this information will receive prompt attention at their hands.

The Havana Metal Wheel Co., Havana, Ill., invite attention to their business in our columns. This firm will be remembered by many of our readers as conducting the largest metal wheel factory in the country. They make a specialty of broad grooved tired wheels, but make almost any sort of broad tired wheels that is desired. In recent years many farmers and teamsters have been thinking of getting these great labor savers. It is a good idea to write these people for directions for measuring your skein, and then order the wheels made to fit exactly. This will enable one to utilize a wagon he may have to good advantage. They also manufacture low truck wagons in metal entirely, also with wood frame work and metal wheels. Our readers who require low broad tired wheels, or the wagons complete, should not fail to write this firm about their latest improved wagons and wheels.

VETERINARY.

Queries in this department answered by DR. A. H. HARTWIG, Watertown, Wis.

Scours in Young Pigs.

What is the remedy for young pigs having scours? E. D. T.
Tillsonburg, Ont.

ANSWER.

Scours in young pigs, as well as in other young animals, is mostly due to errors in feeding the mother. Remove the cause and nature will do the rest.

Mastitis.

I have fine Guernsey heifer due to freshen Aug. 3rd for the first time. One quarter of bag is badly caked and feverish. She seems to be in pain, have milked on that quarter, and there is thick, ropy, bloody milk comes from it. T. H. McC.
Whitewater, Wis.

ANSWER.

It is rather early to milk her at all and expect the contents of the udder to be milk. Bathe the udder with hot water twice or three times daily, about ½ hour at a time. After each bathing apply an ammoniacal liniment and rub well.

Cow's Milk for Colts.—Plethora.

I have a mare due to foal in a few weeks. In case she goes dry when she foals what can I feed the colt?

I have a draft mare when working very hard she trembles and gets played out very easy. I feed her good oats, corn, a little oil meal, some scalded rye and good hay. She is in fair condition and has been fed well all winter.
Racine Co., Wis. SUBSCRIBER.

ANSWER.

You may give the colt cow's milk, but it must be diluted by adding about ⅓ warm water and also slightly sweetened with sugar. Keep this up for at least a month, then you may gradually begin to give the milk undiluted. Let him eat grain and grass as soon as he will in addition to the milk.

The mare appears to be suffering with plethora which is a hypernutritious condition of the blood. Cut out all the grain in your ration when the mare is not working and feed light.

Horse Owners! Use

GOMBAULT'S

Caustic Balsam

A Safe, Speedy, and Positive Cure

"SAVE-THE-HORSE"
—TRADE MARK—
SPAVIN CURE.

POSITIVELY AND PERMANENTLY CURES
Bone or Bog Spavin, Ringbone (except Low Ringbone) Curb, Thoroughpin, Splint, Capped Hock, Shoe Boil, Wind Puff, Weak or Strained Tendons or Lameness.

FROM A REPUTABLE AND NOTED TRAINER

GLENVILLE DRIVING PARK, CLEVELAND, OHIO.
For the enclosed $5.00 please send me one more bottle of "Save-the-Horse." It is doing great work. Respectfully, MILLARD F. SANDERS.

HARTLAND, LIVINGSTON CO., MICH.
Find enclosed money order for $5.00, for which send me another bottle of "Save-the-Horse" spavin cure as it has done all you claim for it for me. With the bottle I bought of you I took off a curb, spavin, and a side bone on a 3 year old mare that other spavin cures refused to help in the least. I consider your spavin cure the best on the market. E. M. PARSHALL.

HOWICK, QUEBEC.
I had a mare suffering from a bone spavin and very lame. I concluded to try a bottle of "Save-the-Horse" and at the expiration of six week's treatment she was free from all lameness and I consider it one of the greatest compounds made. DAVID BARRINGTON.

EDGEWATER, N. J.
Enclosed find check for $5.00 for which you will kindly send me by Wells-Fargo Express one bottle of "Save-the-Horse" as soon as possible. The horse I have been treating with "Save-the-Horse" went sound and I sold him. The last I heard from this horse he was still going sound and working every day, and I think he will stay sound. The bottle I am ordering now I will use on another horse that has a pair of spavins and a curb; he does not go very lame, but walks on his toes and I think "Save-the-Horse" will bring him around so that he will walk all right. Very truly, OTTO MEYER.

The fire iron is uncertain and invariably only aggravates the disease or injury; blistering is less effective than the fire iron, and both necessitates laying up the horse from four weeks to two months. Arsenic, mercurial and poisonous compounds produce irreparable injury.

"Save-the-Horse" eliminates all these factors. Horse can be worked continuously. Cures without scars, blemish, or loss of hair.

It can be applied at any time, anywhere, any place, and in all conditions and extremes of weather—hot or cold. And no matter what the age, condition or development of the case or previous failures in treating, the concentrated penetrating, absorbing power of this remedy is unfailing.

$5.00 PER BOTTLE.

Written guarantee with every bottle constructed solely to satisfy and protect you fully. Need of second bottle is almost improbable, except in rarest of cases. Copy of guarantee sent upon application.

IF YOU HAVE A CASE DIFFERENT FROM INSERTED IN OUR BOOKLET OR ADVERTISING WRITE US.

We will advise you frankly as to the possibility of the remedy effecting a cure. Give explicit particulars, give the veterinary's diagnosis, if he is competent—inform us fully as to the age, development, location of swellings, lameness, action and previous treatment.

$5.00, all druggists and dealers, or sent express prepaid.

TROY CHEMICAL CO., TROY, N. Y.

BLACKLEGOIDS

BEST PREVENTIVE OF BLACKLEG.

Blacklegoids afford the latest and best method of vaccination against blackleg—simplest, safest, surest. They are always ready for use; no filtering, measuring or mixing is necessary. Accuracy of dosage is always assured, because each **Blacklegoid** (or pill) is exactly sufficient for one inoculation. Administration with our Blacklegoid Injector is easy. The operation need not consume one minute. **Blacklegoids** are sold by druggists; *ask for them.*

Our newly printed eight-page folder on the "Cause and Nature of Blackleg" is of interest to stockmen. Write for it; it is free.

—*The Farmer.*

The Price of Dairy Products as Influencing the Abundance of Some Insects.

The economic entomologist sometimes meets with curious and far-reaching relationships in the matter of influences of certain factors that it would at first seem preposterous to associate with insects at all. The threadbare story involving the maiden of uncertain age, cats, mice, bumble-bees and red clover seed, however, sometimes finds a parallel.

That the price of dairy products could have any influence on chinch bugs, or any other species not an animal parasite, at first seems improbable, yet such appears to be the case, so closely are insects connected with some of our industries; and as a seeming accentuation of this fact, we have a similar combination of interests in a different part of the country, involving another insect in precisely the same manner and with the same result.

The dairyman cultivates comparatively little land; prefers permanent pastures and meadows to crop rotation, for the reason that the additional labor required to change his crop from grass to grain and back to grass again increases the expense of his business, without materially adding to his profits. In the northern portion of the country, timothy is the favorite, and, in fact, almost universal meadow grass. In previous numbers of this Journal, I have called attention to the two forms or races of chinch bugs, and pointed out the partiality of the eastern or short-winged form for roots of timothy as a food plant, while the western or long-winged race seldom attacks this grass, and never if it can procure other food.

The short-winged race, once it becomes established in a timothy meadow, does not leave it, but continues to increase and lives by extracting the juices form bulbous root, with the result that the plant discolors and dies. Timothy meadows, within the areas inhabited by this short-winged race of chinch bugs, if left for a long series of years without rotation with cultivated crops, get overpopulated with chinch bugs and the whole meadow is destroyed, whereas a rotation not only destroys a large number of the bugs but serves to keep them reduced over large areas of country. In Jefferson and Essex counties, New York, there is at present a serious outbreak of these chinch bugs in timothy meadows, and this has occured in Ohio in other years. It has been demonstrated that if a crop rotation is generally carried out in a community, this trouble will be prevented.

In Illinois and some portions of Ohio, the long-winged race of chinch bug is the only one present and the timothy meadows, even of long standing, do not suffer from their ravages. But over such areas, the long standing meadows of the dairyman are attacked by other insects, and, though these are in no manner related to the chinch bug, the results are the same. After a couple of years the insects become so abundant as to kill out the timothy entirely, and not only this, but where corn is planted on these grounds, if plowed in spring, the young corn plants are frequently entirely destroyed by the pests that have developed in the field the previous summer. In this case the insect causing the destruction is a snout beetle, which deposits its eggs in the bulbous roots of the timothy and the larvae hatching from these eat out the interior of the roots, killing the grass. In some parts of Ohio I have found this insect very destructive to timothy meadows of several years standing, besides frequently destroying the young corn the following spring, if this was planted. There are some indications that the insect is becoming more numerous and menacing the corn crop over considerable areas. Dr. Forbes has found that in some sections of Illinois, in meadows of two years' standing, from ten to twenty per cent of the roots were affected, and in those that have stood three or four years, from fifty to seventy-five per cent, are affected, but in any case, if land be fall plowed, the beetles will leave the field and not attack the crop that follows the next year.

Thus, lucrative prices for dairy products stimulates dairying; this increases the area of timothy meadows and tends to their continuance for a series of consecutive years. This increases the abundance of these insects and consequently the magnitude of their ravages.—F. M. WEBSTER in *Journal of N. Y Entomological Soc.*

Your Feeble Old Wagon

has many years' service in it. Replace its shaky wheels with

Buy You a Ticket to CROOKSTON, MINN., and call upon

The Polk County Land & Loan Company

For choice Red River Valley Farms. They pay railroad expenses if you buy from them. A few good bargains.

360 acre farm, 4½ miles from Crookston, Minn., (a city of 7,000 inhabitants), and 2½ miles from the State Experimental Farm. This is a photograph of the buildings as they are today: House is 16x24 1½ stories with an L 14x22, and a wood shed in connection 20 ft. square, all on a brick foundation. Barn 28x48, with a lean to 16x48, sheeted both inside and out. Two granaries, one 14x80, and the other 14x42. The buildings are all well painted and in very good repair, and has a fine artesian well. Every acre of this farm in under a high state of cultivation, and is well drained by a slight ravine running through the farm, merely sufficient for self drainage. The soil is a rich deep black loam with a clay sub-soil, and in every respect is considered to be one of the best farms in that vicinity. Our price on this farm is $35.00 per acre.

This is a **320** acre farm about 2½ miles south of the city, this farm is quite well improved, has a very good house of about seven rooms, 1½ stories, barn large enough for ten head of horses, also a good granary, pasture and an artesian well, also has a good well at the house, good grove around the building. This is a very choice piece of land for the price $32.50,

160 acres north-east of the city; this is all hay land, and located in a German settlement, the surrounding country is nearly all under cultivation; we consider this a good piece of land for an investment, this could all be put under the plow, if desired. Price $19.00 per acre.

Comments and Queries from Robinswood Farm.

Breeding Principles Versus Breeders Business Methods.—Power to Judge of Possible Prepotency Must be Based on Individual and Ancestral History.— Line Environmental Influences for the Most Part Determine Prepotency in the Individual.

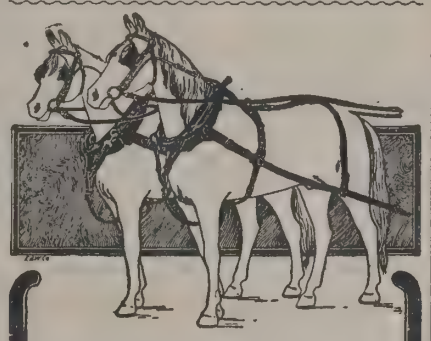
ED. HOARD'S DAIRYMAN: — The editorial on page 1074, issue of Jan. 30th, 1903, entitled "Thoughts on Breeding," was sufficiently suggestive to furnish subject matter for a great deal of comment. The editor was entirely right as to the "broken and chaotic state" of the breeding question, with the exception that reservation shall be made to the effect that there is light ahead, and to be gained, if a sufficient number of breeders will come forward and honestly take an energetic part in collecting and formulating what can be shown to be scientific facts relating to the matter.

We have got far enough ahead with our breeding experimentation at Robinswood Farm, to believe that we know about what can be practically done and what cannot be done, in the way of creating profitable dairy animals.

The possession of the right kind of a dairy cow is the first essential to successful dairying; but it is utterly without a proper understanding of possibilities in the line of breeding effort to believe that there is no limit to the economic productiveness of the cow. I hold that it has been of enormous injury to dairy interests in the aggregate, that for purposes of personal gain, individuals and associations have held up as lures to the dairy farmer, beliefs and ideals that are false and impractical in respect to productive possibilities. As I have gained experience and knowledge as to the business side of the profession of breeding, I have become tremendously disgusted with the situation as I have found it.

The business for the most part and in its most advanced activeness seems in my eyes to be too much based on a foundation of ignorance, or deception, or both. So discouraging has the situation seemed to me, that rather than attempt to contend with a competition hampered by such conditions, I have been tempted to throw up entirely the work that we have been doing through many years, and at a large financial outlay; for there seems to be little chance of a fair recognition by the general public for any honest breeder who knows his business and is really trying to create a best product. However, while there is life, there is hope, and when an outspoken article appears publicly, such as this editorial to which I refer, the despondent soul is somewhat cheered.

I consider that under the present general system of conducting the business side of breeding operations, little, but ultimate disappointment and financial failure for most breeders can be reasonably expected. How many breeders are there who will, or who can give their patrons full information in regard to what ought to be known of an animal in order that it can be used with intelligence for breeding purposes?



Perhaps to the average farmer any cow is only a cow, and no discrimination is made as to her individual powers, or as to the type to which she belongs. Yet there is a tremendous difference in the nature of cows. Some persons even seem to think that a cow with a half mammary development can be fed so as to be made fully productive.

It is the plain duty of the breeder and the seller to inform the buyer just what kind of an individual he proposes to sell, and as to just what the tendencies are in the blood he sells. How many are there who do this? There is no likelihood of its being done unless there is a general demand on the part of the buyers that it shall be done. The policy of holding up freak individuals that have sported away from the average of the type from which they have sprung, as being a type from which equal phenomenal and unusual characteristics can be bred, if done by an intelligent person, is a fraud on those who swallow the bait. I have had my share of experience in this line of being fished for, and feel quite strongly on the subject. I don't think that anyone can catch me with that kind of bait again; but I have not been taken in nearly as badly as multitudes of others have been. It is no wonder that "farmers' prices prevail" and that the millions of dairy farmers in this country are not bidding high for blooded stock; for their interests in such deals have not been sufficiently safeguarded. Yet, if they were in a position to buy intelligently there is no other investment they could make that would return so large a profit to them, even at high prices.

There is no known way in which one can judge that a bull has right prepotencies by a mere visual examination. The individual intensity of being, which can be quite readily recognized by the eye, but which is probably impossible to describe, and which indicates power to impress itself on progeny, may be a prepotency for evil, or for good, or for mediocracy. The possession of a full line history of the animal and its ancestors, and which must be descriptive of weaknesses and deficiencies as well as of merits, is the only basis on which any approach to a correct judgment in the matter can be made. The treatment that the individual animal has received during its life may be of some help in arriving at a determination, especially so far as to probable general vigor in the animal's get is concerned; but those structural and functional peculiarities which are usually reproduced in posterity are those inherited peculiarities and tendencies which have existed in a comparatively long line of ancestors.

In the editorial under comment, the following question, asked at the New York Breeders' Association, was quoted: "Will a cow with a big record be weakened so that her offspring will not be equal to her?" The answer was: "Not unless injured by excessive feeding. Usually the sire is not her equal." The answer is not full enough to cover the question and is misleading. The figures of the record and the strength of digestive power must be considered. The matter of feeding has little to do with the matter.

High feeding does not weaken the progeny unless the cow's health is entirely upset by digestive disorders. Under feeding would be more likely to be injurious in these instances. The trouble in these cases of over-developed mammary powers is usually that the digestive apparatus is not able to furnish enough nutrients for the calf in utero, and for the great out drain through the udder as well. But in most cases of poorer progeny being produced from great producers, the reason is because the tendencies of the back ancestry are lacking in force. The influen-

DON'T be confused by all this talk about White Lead chalking, for this is one of its most desirable properties. Pure White Lead properly applied will not crack, peel or scale, but when it fails will do so gradually from outside wear.

It will protect whatever it is applied to as long as a vestige of the paint remains, and does not require to be scraped or burned off when repainting becomes necessary.

If interested in paint or painting, address

National Lead Co., 100 William Street, New York.

What Prof. Kennedy, Prof. Animal Husbandry Iowa State College, Says About Zenoleum Dip:

"We have used Zenoleum on the College Farm here during the past two years, and have found it to give excellent satisfaction along all lines. We have used it for both sheep and hog dipping purposes. Also as a disinfectant in our judging pavilion. Every farmer should keep a supply of some disinfectant on hand. This is especially important on those farms where stock is being purchased and sold from time to time. On the College Farm we never think of bringing any animals from outside farms on to the same without fully disinfecting them. By so doing we have little or no trouble from disease."

W. J. KENNEDY, Ames, Iowa.

Send for copies of "Zenoleum Veterinary Advisor" and "Piggie's Troubles" and see what others say about it. Books mailed free. Sample gallon of Zenoleum $1.50, express prepaid. Five gallons $6.25, freight prepaid.

"The Great Coal Tar Carbolic Dip." ZENNER DISINFECTANT CO., 34 BATES STREET, DETROIT, MICHIGAN.

ces of the bull must of course always be taken in account. I am inclined to think, though, that in most cases the inherited and prepotent tendencies of all of the ancestors of the bulls used to mate with these freak cows are better than those of the cows themselves.

If we could only propagate these great cows by grafting or division, they could be continued for several generations at least, as is the case with plants that have sported; but in the case of cows, reproduction is a process of new seed formation each time, and in every case the average prepotency of all of the ancestors on both sides fixes the result, while the external influences which have acted on all of these ancestors are the basic influences which determine the nature of the progeny.

I claim that there is not a single case on record of a cow that has sported away from the general average productiveness of her ancestry that has ever thrown a calf her equal, or her better, that has not been mated with a bull that was more than her equal. One might sooner expect lightning to strike twice in one place, than to see an abnormally productive freak cow's progeny sport again to a still greater productiveness. I do not believe that it would be physically possible for a cow's digestive apparatus, by variation in the progeny, to also follow phenomenal development of the mammary apparatus. Such all around developments require that all around evolutionary influences be brought to bear for a long time.

One cannot create something out of nothing. Inasmuch as the causes which produce dairy power in the cow are the influences of her individual environment and those of her ancestors, no large departure from the average effect of such influences can be expected; and inasmuch as there is a limit to the potency of the influences with which we can surround the cow, there is a limit to the productiveness which we may hope for in our progeny.

Really, the starting base, from which we may expect to estimate the limit to profitable productiveness in the cow, is the art and science of growing cow feeds, both as to growing them cheaply, in increasing their digestibility, as well as in securing concentration of form. There is nothing gained in greatly evolving a cow beyond a capacity that is in harmony with the nature of the food she is to utilize. Over evolution has its attendant disadvantages, including the fact that a cow may give so much milk as not only to unfit her from producing the most healthy progeny, but also to absolutely shorten her life materially. The same laws of nature, which pertain to a plant, to a tree, or to a human being, in regard to production, also pertain to the cow.

A certain amount of selfishness of action is necessary in this world, but there is such a thing as losing by attempting to grasp too much, and this general proposition ought to be applied to the cow business. We should be satisfied to accept the product that naturally will be given by a good cow that has a good breed tendency, that has a good family ancestral tendency, and that is given correct treatment in the matter of feeding, protection and general care.

When the various associations have gotten right down to the work of collecting the life statistics of a sufficient number of the good examples of each breed, I think it will be found that cows which weigh 1,000 lbs. at maturity and produce 400 lbs. or less of butter during the best year of their existence, will give birth to much better progeny than those that give larger yields. Every phenomenal cow that I ever heard of, has come out of a well balanced cow of moderate productive powers. I think that one of the underlying, important breeding principles should be, that not too great a product should be expected of the best breeding animals. But as everyone knows, this belief is in direct opposition to the accepted views and practices of many breeders of the present and of the past. Nevertheless, I believe it to be true, and that the make-up of a really great cow comprises points other than the ability to make a big seven day test under forced feeding and exceptional handling. J. M. W. KITCHEN, M. D.

New Hampshire.

Oleo Disappearing.

It is not uncommon to find in the daily papers, items telling with much glee, how the dairymen over-reached themselves in the passage of the oleo bill, as the consumer is becoming accustomed to colorless oleo and the production is increasing rapidly. We notice that when the production was increasing rapidly a few years since, the oleo men like "brerrer rabbit" "lay low" and said nothing. In opposition to these optimistic reports of increased production and consumption the following is interesting:

The anti-oleo legislation has had the effect its promoters desired, which was to drive that product out of use, very largely, if not entirely. It was believed that if oleo were not made in imitation of butter it would not sell, and that belief is justified by fact. During the first eight months of the new law, only 6,000,000 lbs. were made, while for the corresponding period of the previous year the out-put was 74,000,000. The removal of 68,000,000 lbs. of butter substitute from the market has doubtless had much to do with the sustained price of real butter, in the meantime, which has advantaged dairymen, of course; and let us hope that it has not disadvantaged consumers; that that they have lost in paying more for butter, has been made up in satisfaction and better health by eating the real thing instead of a substitute.—*Farm Stock and Home.*

DON'T PUT OFF

Seeing your friends and having them join in for a good club of subscribers.

Wanted to be Heard From!

If there is an invalid woman, suffering from female weakness, prolapsus, or falling of womb, or from leucorrhea who has used Dr. Pierce's Favorite Prescription without complete success, the undersigned proprietors and makers of that world-famed medicine would like to hear from such person—and it will be to her advantage to write them as they offer, in perfect good faith, a reward of $500 for any case of the above maladies which they can not cure.

$3,000 FORFEIT will also be paid if they cannot show the original signature of the individual volunteering the testimonial below, and also of the writers of every testimonial among the thousands which they are constantly publishing, thus proving their genuineness.

WORLD'S DISPENSARY MEDICAL ASSOCIATION, Proprietors, Buffalo, N. Y.

A Massachusetts woman, Mrs. Carrie P. Hannaford, of No. 69 Hale Street, Beverly, Mass., who is well known socially there, being Treasurer of the Order of the Eastern Star, wrote her experience as follows: "Your 'Favorite Prescription' is, without a doubt, the finest remedy on the market to-day, for female difficulties. I suffered for four years with pains every period, and I dreaded the approach of the time as I knew it meant two or three days' misery. Tried several different widely-advertised remedies, and found that they did me no good whatever. One day a friend called, who had suffered as I was suffering, and who told me that she had been cured through the use of Dr. Pierce's Favorite Prescription, so I purchased a package. I found that the real value of your medicine was greater even than my expectations, and the next month I had hardly any pains. The following month had none at all, and found that my general health was much better and new life and strength had come to me."

"Favorite Prescription" makes weak women strong, sick women well. Accept no substitute for the medicine which works wonders for weak women.

The Common Sense Medical Adviser, 1008 large pages in paper covers, is sent *free* on receipt of 21 one-cent stamps to pay expense of mailing *only*. Address Dr. R. V. Pierce, Buffalo, N. Y.

Preserve Your Fences

sills, planking and all other woodwork that is likely to rot, by treating with

Conservo Wood Preservative.

It will pay you to use it on every stick of timber. Costs but a few cents a stick, and saves dollars in repairs, by preventing decay. It also kills germs and insects, and foul smells. We have studied wood preservation for twenty-five years, and believe Conservo is the best preservative that can be made. We *know* it is the best now made.

Send for circular, it costs nothing, and may save much.

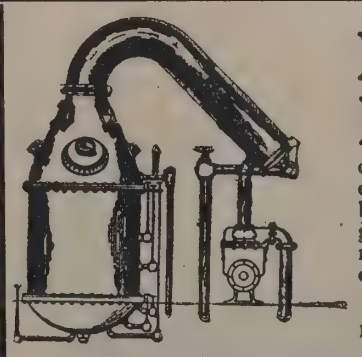
MRS. LEA'S MILK AND BUTTER PURIFIER.

Removes all Weed, Garlic, Vegetable and Animal odor and taint from the milk and in no way injures the cow to which it is fed.

WASHINGTON, D. C., May 27, 1901.



The trial of your "Purifier" made at my request, interests me very much and strengthens my conviction that this "Purifier" is an article which, if it continues to produce the results attained the present season, is destined to be of great importance and value in many dairying districts of this country.

[SIGNED] HENRY E. ALVORD,
Chief of Dairy Division, U. S. Department of Agriculture.

The use of our "MRS. LEA'S MILK AND BUTTER PURIFIER" is a necessity to producers of milk and butter when the pastures are at all infested with Garlic, Onions, Rye or Clover. It is a great saving, as the cows can be grazed, thereby saving largely in feed expenses. It always removes the taints when properly fed. The best dairies are using it largely and with profit. Try it and you will find it to your interest. For sale by The Dairymen's Supply Co., Philadelphia, Pa.; Farmers' Exchange Co, Belle Mead, N. J.; Cook & Brady, Middleton, Del; Filston Farm, Baltimore, Md.; Gardiner Dairy, Balimore, Md.

Manufactured by VIRGINIA CATTLE FOOD COMPANY, Danville, Va.

The Covered Milk Pail.

(Continued from page 314)

of this filth from the milk supply of our cities would result in greatly reducing sickness and death from this class of diseases.

8. The results of these tests indicate that the covered pail is much more efficient for the production of pure milk than is the straining of milk drawn into an open pail. It is quite evident also, that to keep the dirt out of the milk in the first place is much better than to strain it out after the milking. A considerable portion of the dirt dissolves quickly in the warm milk, and thus introduces a contamination that cannot be strained out.

9. These tests were made in a dairy where the conditions of cleanliness are good, as is shown by the small quantities of dirt found even in milk from the open pail. The use of the covered pail would doubtless prove to be more efficient where the conditions were not so good.

This bulletin is to be regarded as a report of progress rather than a complete treatment of the questions discussed, and the station hopes to give more light upon some of the still unsettled problems, in a later bulletin.

Concerning Wood Hoops for Silos.

A Kansas Inquiry.

ED. HOARD'S DAIRYMAN:—I have been a subscriber of your paper for five years. I have found it a mine of information and encouragement. I usually find all questions I wish answered, asked by someone else, so I get my answer in theirs. I have been talking and reading up on the silo. In the last 15 years, there have been between 10 and 20 silos built in this neighborhood and all abandoned.

I have lived here a year and know nothing of it except what have read in HOARD'S DAIRYMAN. Am planting and planning to build one this summer; planting cow peas and corn.

Question 1. In what respect is a wooden hoop superior to iron hoops?

Question 2. Are wooden hoops all right for stave silos without matching, or grooving the 2 inch staves? My plan for wood hoops is to use 2x4 staves, spiking them together as fast as set up, with spikes right through each 2x4, into the one previously set up.

The trouble I see is in not being able to tighten the hoops when required.

I have "A Book on Silage, by Woll, and Buff Jersey's "Hand Book" and the Government Agricultural Report on silos, but none of them mention wooden hoops, but in recent issues of your good paper, I see them spoken of as better than iron.

An early reply will be greatfully received as I wish to get material and have it dry. F. L. HILL.

Olathe, Kansas.

1. The answer to Question 1 is that the wood hoops are supposed to cost less than iron hoops.

2. We should hesitate to use the wood hoops under the conditions named, and for the reasons stated. With wood hoops we should either tongue and grove the staves or use double thickness of boards with the acid proof, P & B paper between them.

Kicking Cows.

ED. HOARD'S DAIRYMAN:—I have seen a number of articles in your paper on different methods of handling kicking cows, but none I think which is so easily applied so simple and so effective as the following: Take a quarter inch rope and tie a slipping noose in one end, put it around the cow just in front of the udder and over the points of the hips, draw moderately tight and tie. The cow can't kick the milker because when the lower part of the leg moves forward the point of the hip moves back drawing the rope still tighter. The rope should not be drawn very tight, as if it is, the cow in attempting to move is liable to fall upon the milker. SUBSCRIBER.

35.75 For our *"Leader" 3-Spring Wagon.* 1 1-16 axles; double reaches well ironed; iron hub, all hickory wheels; spring cushions; Pegamoid leather trimming; nicely finished. *A mighty good wagon at a mighty low price.*

38.50 For *Young Man's Fancy Buggy.* A general favorite. The price is less than your dealer pays for such in car lots. Long distance axles: selected hickory wheels; genuine leather quarter top; trimmed in fancy velour; side panel of body painted a dark maroon. A beautiful job in every way.

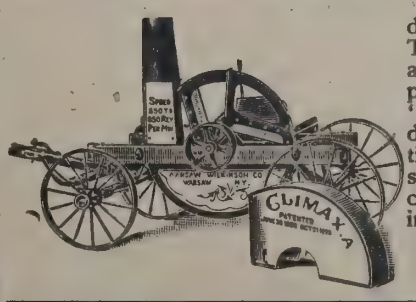
42.50 For our *"Brown Beauty" Buggy.* One of the *choicest* in the line. Brown panels on body; brown cloth trimming; brown head lining; red gear; long distance axle; new style upholstering. *A nobby rig at a low price.*

44.90 For our *"New Thorneward" Buggy.* More of this style sold than any other. Long distance axles; Bailey loops; all-wool cloth trimming; elegant finish. *You could not duplicate it from your dealer for $65.00.*

46.50 For our *"Lakeside" Triple-Service Surrey.* A large, roomy, full panel back, spring cushioned surrey which can be used also as an open driver or one seat wagon with room behind for trunks, etc. *All for the price of a buggy elsewhere.*

69.85 For our *"Peerless" Buggy.* The pride of our factory. Has all the essential features of the very highest grade work. Usually sells for $25.00 more than price quoted. *You will be proud of it anywhere.*

We Allow No One to Undersell Us—Quality for Quality



The vital point in a purchase is not entirely WHAT YOU PAY, but WHAT YOU GET for your money. Remember we guarantee to absolutely satisfy you or we will refund the purchase price, and pay the freight both ways.

The Farmer Who values his crops

is naturally interested as to the results which his harvesting may bring. He sometimes lessens his chances for gain by using harvesting machines that are liable to go against him when he needs them most, necessitating expensive repairs, cost of which would reduce some of the profit he figured on. This can be avoided by using the reliable

"Milwaukee" Machines.

They are skillfully constructed, insuring superior working qualities and meet all requirements in the field. Their ease of operation both by man and team lighten the farmer's labors, as they contain all the elements necessary to successful machines. The best mechanical features are represented in all "Milwaukee" Binders, Mowers, Reapers, Corn Harvesters, Rakes and Sickle Grinders. Our local agents carry them; call and look them over

SAVE MONEY

OR LOSE MONEY, WHICH DO YOU DO?

Some people save money because they think, because they have brains and use them. Others lose money because they don't think, because they let some other fellow tell them what to do. Many people have looked into our new plan of selling the **1903 Suspended Bowl Factory Tubular Separator** and have saved a nice sum of money by doing so. Others are losing money by listening to the "fairy stories" of competitors who are doing their utmost to prevent creamerymen from trying the **Tubular**—the fellows who don't think. A trial of the **Tubular** means that the creameryman will want to keep it, and since any responsible creamery operator in America can have one of these new style separators on trial, without the slightest obligation to buy or keep it, what possible reason can there be for not finding out whether or not they are better than other separators? Can you tell? Would you like to hear from some of the people who think, and who have tried the **1903 Tubular?** Write us and we will give you their names. Wouldn't you like to know more about this new separator and our new plan?

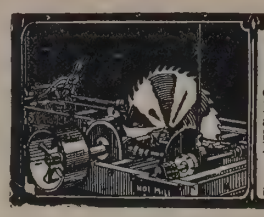
A Problem in Ventilation.

ED. HOARD'S DAIRYMAN:—I have a problem in ventilation that is bothering me, and as I know of no better authority on all matters connected with dairying, than HOARD'S DAIRYMAN, I come to you to help me out of my dilemma. I have been raising up an old barn and putting a stable under it. New sills are put on the wall, and posts put on them to the old sills. There will be an air space of ten inches between the outer and inner covering. I want to put my ventilators in this air space but cannot see how I am going to get around the old sill. My stable will be but 28 feet in the clear, so I cannot afford the room to put them on the inside in the alleys. Can you help me out? I want proper ventilation and would be grateful for any suggestions you may make in the matter. I am going to put in your Model Stall. How long do you make them, from front to gutter? Do you think it necessary to put in a gutter? The stable will be 28×120, 8 feet high. I should be pleased to have your idea as to the proper arrangement of the interior. I want stalls for 50 cows and three or more box stalls. Will you kindly give me an early reply as I want to finish my work before haying. B. C. T.
Boonville, N. Y.



The above problem in ventilation gives us much less concern than the limited width of the stable. So far as ventilators for taking off the cold and foul air are concerned, they can very readily be placed outside the building, and the ten-inch space between the outer and inner coverings is just what is needed to provide ingress of fresh air. These intake flues in this space should open outwardly from three to six feet lower than the ceiling of the stable and inwardly just below the ceiling, and be provided there with a slide to regulate the amount of inflow. We would prefer to have several of these intake flues on both sides of the stable, rather than to depend upon a few larger ones, because in that way the fresh cold air is better distributed throughout the stable, than where it enters at only one or two or three places. For the ventilating shaft proper, provision should be made for a sectional area of four square feet for each twenty cows, which is ten square feet for fifty cows. Build on the outside of the barn, a flue or chimney two feet by five feet on the inside, and let this extend up past the eaves a little higher than the ridge of the barn. Preferably, this should be located as near as possible to the center of the building, and it might be well to provide such a flue on either side so as to take advantage of the shifting winds. Let there be an opening at the bottom, level with the floor of the stable, and another one just below the ceiling of the stable to let off the hot air in summer, both of them provided with slides to regulate the outgo of the air according to circumstances.

Now as to width of that stable, would it not be practicable to build on an addition, say five feet wide, the entire length of the barn, and thus make the stable about 33 feet wide on the inside? Without this addition, our correspondent will always be troubled for room; but with it, he can arrange his stable so as to have the cows face either outward or inward, and have just sufficient room to carry on all stable operations comfortably and economically.

Method of Raising Vetches.

An Oregon Farmer gives the following method of raising vetches:

"I first plowed seven inches deep. In February, sowed 80 pounds of vetches, 60 pounds of oats and 10 pounds of clover to the acre, harrowing three times after sowing. Planting was done in 1901, and since then I have received two crops a year. Off the first cutting enough vetches were obtained from a seven-acre field to make 10 tons of hay and fill a silo containing 100 tons of ensilage. On the second cut the first year, 15 tons of hay were obtained. Last year 25 milch cows were fed on the crop from June 1 to August 15. This year the crop will average two tons to the acre. Last year and year before last 50 pounds of land plaster to the acre were used."

MRS. LEA'S MILK AND BUTTER PURIFIER.

Removes all Weed, Garlic, Vegetable and Animal odor and taint from the milk and in no way injures the cow to which it is fed.

WASHINGTON, D. C., May 27, 1901.

The trial of your "Purifier" made at my request, interests me very much and strengthens my conviction that this "Purifier" is an article which, if it continues to produce the results attained the present season, is destined to be of great importance and value in many dairying districts of this country.

[SIGNED] HENRY E. ALVORD,
Chief of Dairy Division, U. S. Department of Agriculture.

The use of our "MRS. LEA'S MILK AND BUTTER PURIFIER" is a necessity to producers of milk and butter when the pastures are at all infested with Garlic, Onions, Rye or Clover. It is a great saving, as the cows can be grazed, thereby saving largely in feed expenses. It always removes the taints when properly fed. The best dairies are using it largely and with profit. Try it and you will find it to your interest. For sale by The Dairymen's Supply Co., Philadelphia, Pa.; Farmers' Exchange Co, Belle Mead, N. J.; Cook & Brady, Middleton, Del; Filston Farm, Baltimore, Md.; Gardiner Dairy, Balimore, Md.

Notes from Wisconsin Experiment Station.

Boric Acid in Dairy Salt—Condensed Milk.

Ed Hoard's Dairyman:—The following letter was received from a large Wisconsin creamery company a short time ago, accompanied by a sample box of salt (so-called), as stated in the letter:

"One of our customers in the South has sent us a barrel of salt which, they claim, has been treated by a secret process of theirs, but that it is absolutely pure and there is nothing added to it. The claim for this process is that the butter will keep fresh and sweet for an indefinite period. They state that a test made by them sometime ago of a sample quantity of butter salted with this salt, the butter was placed in an incubator and held at a temperature of 80° for a period of 90 days, and that at the end of that time it was fresh and sweet and free from any rancidity whatever. They further state that their experiments have covered a long period of time and that they have used in the many different tests over 400 tons of salt before they obtained the present results. They write that they would like to have us experiment with this salt, and also that they would like to have our Experiment Station analyze it and experiment with it. If you are inclined to give this a test, advise us. We are sending you by freight, charges prepaid, a sample box of this salt. We would like to know if there is anything in it that conflicts with our state laws before giving it a trial or experimenting with it at our creamery here."

The salt was subjected to qualitative tests for boric acid and this was found present therein in appreciable quantities. The statement of the manufacturers that the salt is absolutely pure and that there is nothing added to it is, therefore, not in accordance with the facts of the case.

Anyone who is at all familiar with the action of salt upon butter might also know before hand that it is not true that butter can be kept "fresh and sweet and free from any rancidity whatever" for ninety days at a temperature of 80 degrees by the use of absolutely pure salt. The best grades of butter salt are pretty near chemically pure salt, and the small amounts of impurities found in these, do not, so far as is known, affect the keeping quality of the butter salted therewith to any appreciable degree.

A small admixture of boric acid to the butter or to the salt does, however, check the growth of the bacteria which cause butter to turn rancid and if it was not for the probable injurious effect of this preservative on the health of persons eating food so dosed, its use would be an advantage. But in view of the position of the best authorities among medical men and physiological chemists in regard to this subject, boracic acid cannot be safely used as a preservative for food materials and the laws of a number of the states in the Union prohibit its use for this purpose. The Wisconsin statutes of 1898 thus provide that

"Any person who shall sell or offer for sale, consign or have in his possession with intent to sell any milk, cream, butter, cheese or other dairy products, or who shall deliver to any creamery or cheese factory, milk or cream to be manufactured into butter or cheese to which milk, cream, butter, cheese or other dairy products, boracic acid, salicylic acid or compounds containing them, or other antiseptics injurious to health have been added, shall be punished by fine, not exceeding one hundred dollars nor less than twenty-five dollars."

I wish to bring this matter before the creamery men among the readers of your valuable paper so that they will not be taken in by this or similar schemes and thus unknowingly come into conflict with the laws of the state.

Condensed Milk.

A sample of condensed milk labled "The Gail Borden Eagle Brand" manufactured by Borden Condensed Milk Co., New York, U. S. A., was recently submitted to us for analysis by parties in this state who are considering the question of starting a milk-condensing factory and who wished to know just what is the composition of one of the leading brands of condensed milk at the present time. The sample analyzed was bought in the local market. Its chemical composition was found to be as shown below; to forestall criticism I may say that the methods of analysis followed were those adopted by the Association of Official Agricultural Chemists, and that all possible precautions were taken in the analysis of the sample so as not to permit of doubts as to the correctness of the results obtained.

Specific gravity	1.3002	
Water	20.20	per cent
Total solids	70.80	" "
Fat	6.25	" "
Casein and albumen	7.69	" "
Milk sugar	25.95	" "
Cane sugar	28.91	" "
Ash	2.00	" "

A calculation shows that the milk had been condensed to very nearly one-fifth its original volume and the fat content of the original milk must, therefore, have been about 1.52 per cent, on the supposition that this contained 9 per cent, of solids-not fat, which is quite certain not to be much out of the way. If the milk bought by the manufacturers was of average composition and contained toward 4 per cent of fat, nearly two-thirds of the fat contained therein has, therefore, been skimmed off prior to the condensation of the milk.

There cannot be much said against such a practice if the public buying and using the milk are acquainted with the fact. Nothing is said on the label on the can, however, about the milk used in the manufacture of the condensed milk being largely skimmed. On the contrary, we are informed that "this preserved milk is condensed milk, combined with best refined sugar, and is the same article as that sold forty years prior to 1899 by the New York Condensed Milk Co."

This last statement is not born out by former analyses of this brand. For instance, analyses made by the Canadian Inland Revenue Department in 1897 and 1900; nine samples analyzed in 1897 contained 5.92 per cent fat on the average and as this milk was condensed to about one-third its original volume, the fat content of the milk was 2.42 per cent. In the same way the average fat content of 23 samples analyzed in 1900 by the Department mentioned came at 8.78 per cent, with 3.50 per cent in original milk. Analyses of the Eagle Brand, made by the Massachusetts Board of Health in 1900, show a fat content of 9.75 per cent in the condensed milk and 4.24 per cent in the original milk, and according to an analysis published in the report of 1901 of the Board, this brand had a fat content of 7.38 per cent. In no case has, therefore, such a low per cent of fat been found in the original milk as in case of the sample analyzed by us, nor has the condensation been carried so far in samples previously analyzed, as far as we are able to judge from the reports published.

The composition of the condensed milk is not a matter of great importance to a healthy adult, from the point of food value, only he is not getting what he thinks he is, but the matter stands entirely different when the condensed milk is used for the feeding of infants. The directions on the can say that for infants, 14 to 16 parts water is to be added to one part of condensed milk during the first month and the amount of water added is decreased gradually as the child grows older until at the age of 10 to 12 months 6 to 7 parts water to one part of condensed milk may be used. Medical men would say without hesitation that it would be to put infants on a starvation diet to feed them on condensed milk of the kind in the tin analyzed diluted 14 to 16 times its volume with water, as given on the directions. The unfortunate infant would not be able to take up enough food materials in such diluted solutions to cover the absolute needs of the body, to say nothing of gaining in weight.

The brand of condensed milk analyzed by us is considered one of the leading brands now on the market; our results certainly show the need of looking into the composition of the other brands on the market as well as, in justice to the manufacturers of this sample, of analyzing a number of different cans of this brand. As the subject of human foods lies outside of the proper sphere of activities of our department, I have called the attention of the State Food and Dairy Commission to the matter and am pleased to state that they are preparing to take up this work in the near future. The influence of the publication of the results of such an investigation can only be healthy and will be likely to make the use of cream separators less popular in milk-condensing factories. I hope that the day is not far distant when we may have a National pure-food law on the U. S. Statutes and this, among other things, will provide for a standard of at least 12 per cent solids in milk used for the manufacture of condensed milk, of which one-fourth shall be butter fat.

F. W. Woll
Wisconsin Experiment Station.

The Dual-Purpose Cow.

While so much is being said about the general-purpose cow, why is not more said about a scale of points by which she in perfection may be known? Why don't our state fairs have a general-purpose class in which this general-purpose cow can appear, that the people may know what she looks like? The believers in this cow should certainly do more toward making known to the public just what she is. Should not the agricultural experiment stations make this a subject of experiment and investigation?

The general-purpose cow has been the cause of much heated discussion. Prominent agricultural authorities have been arrayed against one another in discussing the pros and cons of this general-purpose proposition. It is time that we have something more tangible. One side has claimed that she does not and never would exist, while the other was as positive in claiming that she was here in great numbers, and that she could be bred to a certainty. Although this controversy has been going on for many years, we did not know, until recently, of a single instance in this country where a breeder claimed to be a breeder of dual-purpose cattle, and manifested by practice that he was sincere. We have repeatedly seen herds advertised for both milk and beef, but have later found the calves running

Why the Butter Don't Come.

We have been frequently asked to give reasons why the butter don't come. For the most part we have confined our replies to suggestions as to the ripeness of cream, period of lactation and temperature of churning. The above, copied from the *Inland Printer*, shows a reason why the butter does not come, that we have failed heretofore to take into account. It seems to be a valid reason.

with the cows, and no attention whatever paid to the milk side of the question. The time has come when this matter should be put on a more definite basis.

We do not wish to be understood as taking sides on this question, for with all the eminent authority on both sides, we can plainly see that the problem has not yet met with a thorough solution. Nevertheless, we believe that it is time that something be done towards solving this problem. Farmers want general-purpose breeding stock, and if such exist they should have a chance to know what they look like, and the breeders should have an idea of what to breed for. Until such an idea is better known the breeding of general-purpose stock is liable to be very much of a haphazard undertaking.

Of all the Short-horn breeders in Minnesota, Blackmer & Nelson, of Albert Lea, and James Stewart, of Montevideo, are the only breeders that we know of who are paying special attention to the milking side of their full-blooded Short-horn herd. Their animals are chiefly of Bates breeding. Their calves are not allowed to suck, the cows are milked, and the annual production of each cow is approximately known, and the calves, after the first few weeks, are reared on skim milk and grain. There may be others who are following this practice. However, if such is the case they have not made their presence known. We hope in the future to hear what the dual-purpose cow is doing at the pail as well as at the block. We have asked R. C. Blackmer, who is making a specialty of breeding general-purpose stock, to give us a descriptton of the general-purpose Short-horn cow that he is aiming to produce in his Short-horn breeding. As he is one of the first to set up a standard of excellence, we herewith give his description of what he considers the ideal conformation of the dual-purpose Short-horn cow.

He says: "She should carry the straight, beefy back, and straight meaty hindquarters. The rear quarters should be set wide apart, to allow room for a capacious udder, which should be large and square, with well placed teats. She should have large milk veins, and large milk wells. She should have somewhat more of the open organization than the straight beef type, in other words, she should not be as compactly built as the special-purpose beef cow And there should be an exceptionally long distance from point of hip to first rib, and the ribs, especially the last two, should not be set very close together. Her head should be spare, with that feminine, motherly appearance so much admired in the dairy breeds. She should have the live, velvety touch peculiar to all stock that are economical feeders, and she should weigh not less than thirteen hundred at maturity."

In the above description there seems to be but little to interfere with the laying on of high priced flesh, and the milking functions are not seriously hampered. This is the beginning, on the part of Mr. Blackmer, of establishing a dual-purpose type in his own herd, and the dual-purpose advocates will be doing the breeding interests a great service by uniting with him in fixing on a definite standard for both males and females.—A. W. TROW in *St. Paul Farmer.*

The Necessity of Farm Accounts.

[Paper Read Before the Salem Co., N. J., Board of Agriculture by MISS JESSIE COLSON.]

We have listened to numerous discourses on various farm topics, but we have never listened to one on the necessity of farm accounts, and yet they are the foundation upon which most of the discussions are based. When Prof. Vorhees talks to us about cows, and Prof. Smith about insects, do they not speak from the financial standpoint—Will it pay? Just as they keep an account to know whether their experiments are practical, so should every farmer keep an account to know whether his methods are sufficiently remunerative.

Every business man is supposed to have his own methods of keeping his accounts and, of course, they are for private information. While those engaged in mercantile and other pursuits usually keep accounts, is it not true that farmers, as a rule, do not keep accounts? Whenever they enter into a transaction the other party usually keeps the account, and when settlement day comes there are often misunderstandings and difficulties. Every farmer, in justice to himself, his family and his estate, needs to keep an account; to carefully file away every year receipted bills, tie them in bundles and mark the year on the outside.

Also, preserve the account you keep with your help, so that where there is no bill there is an account showing date and amount paid. Servants have been known to hand in bills for unpaid wages after a death, when such an account has proved their claim to be false.

There is no reason why a farm account can not be kept as easily as accounts in other occupations. What seems difficult at first will become easy with a little practice, care and patience. The result will amply repay the time and trouble expended. It will be a valuable reference from time to time, a revealer of little leaks and a basis to plan future expansion along special lines.

It is decidedly best for the farmer to keep his account, but if he does not wish to do so, rather than not have an account, let his wife or some other member of his family keep it. When kept by the wife it enables her to see how the money comes and where it goes; it leads her mind more in thought with her husband, thus making it possible for them to work together in greater harmony toward a given object.

An account kept with each child would reveal unthought of truths and make the children more careful of their clothing and other financial demands. There would be a business basis established in the household. Figures and facts would stand in the place of imaginary extravagances and excessive home expenses. There would be a basis upon which to figure for reducing expense and increasing income. An account makes possible a company or family trust with the division of labor, the accompanying responsibility and remuneration.

A farm account has a moral and intellectual effect upon the farmer's family. Its moral effect consists in trying to be accurate, upright and honest; its intellectual value is in the mental efforts in keeping the account and in solving the various problems involved.

To keep an account with each child, each animal, each crop, and every employe, would be quite an extensive system of book-keeping. While it is possible, and I believe practical, to keep an account with the various crops of corn, wheat, potatoes, tomatoes, horses, cows, sheep, chickens, etc., I do not think it advisable to undertake so much the first year; but it is advisable to keep an account. Make a beginning! Let your bank book be your model.

On one page write all expenses, with date and item; on the opposite page write receipts with name of article sold, date, price, quantity, etc. At the end of each month, balance the account and carry the balance to the next month; at the end of the year you will know how many dollars you have received and spent and what for. Try to pay and try to collect every bill possible during the month. Whenever you buy an article and do not pay for it, be sure and take a bill for it and when you do pay have it receipted, to be carefully filed away with the other bills of the year. In case of a store account, have a book and take care to keep it accurate.

The first of April is a very good time to take an account of stock, because it is the beginning of the farming year. Make an appraisement of your belongings just as though you were doing it for some deceased friend. This record, with the year's account of expense and income, will give a very fair estimate of your year's success and your financial standing. From the day book you can check off and enter in another book any class of articles you may wish to sum up for the year, such as living expenses, wages, fertilizers, feed, incidentals, etc. Such accounts are interesting to compare from year to year. They are valuable for reference and an incentive to try to do better another year.

Book-farming has often been spoken of in a slighting way, but the time is fast approaching when accurate business methods must be practiced by every farmer who wishes to be successful and maintain a position of equality, socially and financially with his brothers in other professions and occupations.

Probably the numerous failures of book-farming have been due to the omission of a book account and the lack of good judgment. It is possible at the present price of feeding stuffs to buy feed for cows, with the idea of increasing the milk flow and, therefore, the income, and be running in debt by the transaction. An account before and after would surely be worth the trouble and a sure cure. Do you remember Ditrich saying "the cows ought to keep the farm and the farm the cows?" If they cannot do that much, they had better be sent to the block.

Every year farming becomes more intensive. Greater care and more concentrated thoughts are demanded. As the successful farmer of the past combined mental arithmetic, good judgment and careful execution, so likewise must the successful farmer of the present and the future, but he must transform his mental arithmetic into book-keeping, his personal experience and observation must extend beyond his narrow fields into the broader fields of creation, and his execution must be guided by the fairy hand of science.

The Overrun From Cream.

What Should It Be?

Quite a few creamery patrons here are putting in DeLaval hand separators and I among others. Ours is a Baby No. 2. It is doing excellent work. We find it very much better to get our skim milk at regular hours twice a day, to feed sweet and fresh from separator, than to get it returned about noon from the creamery in a sour condition. Our cream can is placed in a spring branch where it quickly cools and reaches the creamery sweet.

Our creamery does not buy our milk, but we pay them a stipulated price per pound for manufacturing and marketing the butter. The cream is tested by Babcock machine. The sample of cream for testing is weighed, 18 grams being the amount taken. Now we refer the question to you as to what the practiced overrun should be as between creamery man and patron. For example: 153 pounds cream, test 37 per cent fat, and 189 pounds testing 33 per cent fat.

The creamery man and patrons are trying to arrive at a just determination of this question of overrun from a practical standpoint. A. M. STEVENS.

Ellensburg, Wash.

The amount of overrun to be expected from fat in cream will depend very much upon the character of the butter produced. As is well known, commercial butter is not wholly pure fat, but contains more or less water, salt and curd. The curd and salt may be considered as fairly constant, but the water content of butter varies quite widely. In eight hundred samples taken from four hundred creameries in eighteen different states of the United States in 1902, the amount of water varied from 7.2 per cent to 17.62 per cent, the average being 11.78 per cent. If we allow 12 per cent for water, 3 per cent for ash (principally salt), and 1 per cent for curd,—16 per cent in all,—there will remain 84 per cent of pure fat in the butter. On this basis of fat, making allowance for a minimum loss in churning, say two-tenths of one per cent, the increase for 37 per cent cream would be 19 per cent. If the butter contained only 82½ per cent of butter fat, the overrun would be 20 per cent. If the butter contained 85 per cent fat, the overrun would be about 16¾ per cent. In view of all these figures, we have considered 18 per cent overrun as quite within possibilities for any modern creamery equipped with up-to-date machinery and presided over by a competent butter maker.

On this basis, 153 pounds of cream, testing 37 per cent fat, should yield 66.8 pounds of standard commercial butter; and 189 pounds of cream, testing 33 per cent fat, should yield 73.6 pounds of butter.

Alfalfa Don'ts.

Don't sow alfalfa on poor soil.

Don't sow alfalfa on wet soil.

Don't forget to clip it three times the first year.

Don't turn any stock on it till the next May.

Don't let alfalfa hay get dry before raking.

Don't fail to cut your hay in time. That means to be ready to cut by June first.

Don't ever let stock on your alfalfa meadows in cold weather.

Don't sow alfalfa seed on unprepared soil, as you do clover.

If it fails with you, manure the land and try again.—JOSEPH E. WING, in *National Stockman and Farmer.*

All Humors

Are impure matters which the skin, liver, kidneys and other organs can not take care of without help, there is such an accumulation of them.

They litter the whole system.

Pimples, boils, eczema and other eruptions, loss of appetite, that tired feeling, bilious turns, fits of indigestion, dull headaches and many other troubles are due to them.

Hood's Sarsaparilla and Pills

Remove all humors, overcome all their effects, strengthen, tone and invigorate the whole system.

Testimonials of remarkable cures mailed on request. C. I. HOOD CO., Lowell, Mass.

THE MARKET MAN KNOWS BUTTER

quickly absorbs odors from other articles kept in his shop. He knows also how perfectly good butter is preserved and how surely his patrons are pleased when it is wrapped in our

Pioneer Brand

Parchment Paper.

It preserves for long periods the purity of the butter, keeping in all its natural sweetness and flavor, and shutting out everything that would taint or cause it to become rancid. It is purely a vegetable paper, without smell or taste. Your name, trade mark, or dairy may be printed on every package, and it will never rub off or discolor the butter. While it protects your good butter it makes and preserves for you a good name. Send for samples and ask for copy of our booklet, "Better Butter." All sent free.

My Experience in Feeding Alfalfa to Hogs.

[Extract from paper read before the Interstate Swine Breeders' Association at Lincoln, Neb., by G. H. PAYNE of Omaha.]

Alfalfa is a great subject. The more you see of alfalfa, the more you hear about alfalfa, the more you want to talk about alfalfa. It is one of the handsomest field plants that grows, being the first thing to show green in the spring and the last to lose its beautiful color in the fall. The sheep love it, the cattle live on it, the chickens grow fat on it, the pig will run for it. It is claimed (?) the Mormon makes tea of it and the Indian smokes it—but perhaps you can take the last two statements with a few grains of salt.

My experience in feeding alfalfa to hogs is not extensive, although I have studied the subject very carefully for the last few years, being interested for some time in a small ranch at Sidney, Neb., where we run about 2,000 cattle and put up from 1,000 to 1,200 tons of alfalfa per year; and also being interested in several farms at North Platte and Lexington, in the heart of the alfalfa belt.

Wishing to satify ourselves more fully on the subject, we determined, a year ago, on our farms at North Platte and Lexington, to make a thorough test of the value of alfalfa for hogs. I can describe our progress no better than by quoting from a report we issued on Nov. 23, 1902, as follows:

HOGS ON ALFALFA—EXPERIMENTS CONDUCTED ON THE SUMMER RANCH

NORTH PLATTE, NEB.

On the above farm there is a small tract of land, 21 acres old alfalfa, and 5 acres new alfalfa, sown in 1902; total, 26 acres.

The first crop of alfalfa was cut June 1, and from that time up to date has been pastured with an average of about 160 head of hogs, all ages.

In addition to running 160 head of hogs on this 26 acres of land, the hay was cut three times, making a total of 88½ tons of hay. This was sold to a cattle company and fed out on the property, we doing the feeding, at $5.00 per ton, netting the owners of the property over $13.50 per acre for the alfalfa, in addition to pasturing, as above stated, 160 head of hogs. The hogs were weighed on the 14th day of each month, with this result.

EXPERIMENT WITH 59 STOCK HOGS.

June 14, weighed an average of 108 pounds each.

August 14, weighed an average of 144 pounds each.

This was a gain of 36 pounds each in 60 days, or .6 of a pound per day. These hogs were fed, as near as could be measured, one-half pound of shelled corn per day, the gain in weight per day being greater than the grain fed. A very satisfactory showing, the gain costing less than one cent per pound for grain fed.

EXPERIMENT WITH 30 SHOATS.

August 14, weighed an average of 131 lbs. each. They were put in separate pastures and fed about 4 lbs. of ground wheat and rye per day, with all the alfalfa they wanted to eat.

Oct. 14th, weighed an average of 190 lbs. each. This was a gain of 59 lbs. in 60 days, or practically 1 lb. each per day. This experiment showed an unsatisfactory gain in comparison with the large increase in grain fed, but the only solution we can give is that the ground wheat and rye, fed with the alfalfa, was not as good a balanced ration as corn fed with alfalfa, and that where the grain was increased they ate that much less alfalfa.

EXPERIMENT WITH 22 THOROUGHBRED DUROC JERSEY GILTS.

Sept. 14th, weighed an average of 100.1 lbs. each.

Nov. 14th, weighed an average of 151.3 lbs. each. This was a gain of 51.2 lbs. each in 60 days, or .8 of a pound a day. These hogs were fed one pound of ground wheat and corn each per day, and alfalfa pasture.

This is considered the best gain of all the experiments, .8 of a pound per day being considered a very large gain with such a small grain ration and the grain being wheat and corn. These hogs were in excellent flesh and took very heartily to the alfalfa pasture. The small ration of grain named went direct to gain, almost pound for pound.

It is generally conceded that it takes from four and one-half to six pounds of grain to make one pound of pork. The experiments above prove, beyond all question of a doubt, that a gain of one pound of pork can be made with from one to two pounds of grain and such alfalfa pasture as a hog will eat.

IN CONCLUSION.

First, we do not believe hogs will thrive on alfalfa hay alone, nor do we think it pays to expect young pigs are going to do well on alfalfa pasture only.

Second, we do believe that you can turn shoats on an alfalfa pasture in the spring, and with one pound of corn per head per day make a gain of one-half to three-quarters pound per day, or from 125 to 150 pounds during the six months grazing season, which is making pork at a low cost.

Third, we also believe from experiments we have made, that by chopping alfalfa hay (this must be good hay where the leaves have been preserved) and mixing this with ground corn, at the rate of about one pound of corn to five or six pounds of alfalfa, that it will make a ration that will carry stock hogs over the winter as satisfactorily to the owner as the ordinary ration, mostly of corn, at one-third the cost, and the animal will be in better condition to ward off disease.

Alfalfa, particularly the Turkestan, is gaining small footholds all over the Dakotas, and its possibilities are of growing interest.

Siloing Alfalfa. Getting a Profitable Herd.

I am a subscriber but a short time, but I read every number with great interest and derive much benefit from it.

The silo question is very interesting to me and wish very much to build one as soon as I can.

I have about 50 acres of alfalfa. Would it not be the best way to feed it from a silo. It, in the dry form, is the only feed excepting grass, that I depend upon, to produce milk.

I have 20 cows of variable breeds—none of the special dairy kind. Do you think it would be practicable to sell off those I have and buy good grade Jerseys and breed up from them? S. S. Gill, Kans.

Various of our correspondents in California, and other sections where alfalfa has been raised for some years, write us that they have met with great success in putting alfalfa in the silo, and we are so persuaded of the practicability of doing this, that we shall ourselves try it this season, if the weather at the time when the first crop should be cut is not favorable for curing it. We would not advise our correspondent to think of making the entire crop from his fifty acres into silage, but would reserve two or more of the cuttings for hay.

We would not advise the selling off of the present herd of cows as a whole and substitute grades of any description, but we do unhesitatingly advise the adoption of a thorough system of bookkeeping in connection with the cows now in the herd. Weigh the milk of each cow at every milking and have it tested for quality once or twice a month and thus determine which of the cows in the present herd are profitable and which are not profitable. Dispose of the unprofitable cows and keep the others. Secure a first-class bull to head the herd and thus raise a new herd which, in all human probability, will exceed in quality, as an average, anything that he can purchase.

"ADVERTISEMENT".

FROM THE BENCH.

A Judge Commends Pure Food,

A Judge of a Colorado Court said: "Nearly one year ago I began the use of Grape-Nuts as a food. Constant confinement indoors and the monotonous grind of office duties had so weakened and impaired my mental powers that I felt the imperative need of something which neither doctors nor food specialists seemed able to supply.

"A week's use of Grape-Nuts twice each day convinced me that some unusual and marvelous virtue was contained therein. My mental vigor returned with astonishing rapidity; brain weariness (from which I had constantly suffered) quickly disappeared; clearness of thought and intellectual health and activity which I had never previously known were to me the plain results of a few months' use of this food.

"Unhesitatingly I commend Grape-Nuts as the most remarkable food preparation which science has ever produced so far as my knowledge and experience extends." Name and address furnished by Postum Co., Battle Creek, Mich.

The judge is right. Grape-Nuts food is a certain and remarkable brain builder and can be relied upon. There's a reason.

The heavy old milk cans are covered with dust,
All piled up in grim array.
Their mission is ended—on the shelf let 'em rust,
We work in the EMPIRE WAY.

The Cat is Watching.

Tabby, of course, does not understand why it is so. Perhaps she remembers the days when Molly thought it was a day's work to wash the cans and pans they kept the milk in. Molly knows though that it is the

Empire Cream Separator

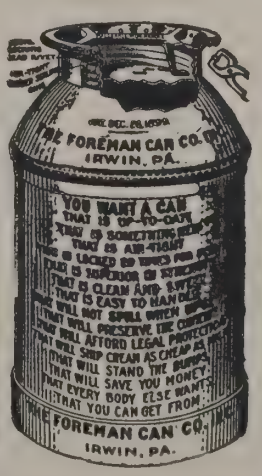
that lessens the work and keeps all the profits of the dairy right at home. The sweet milk is left for feeding your stock. There is money in most separators, but the most money in an **Empire.** It is the simplest in construction, the lightest running, the easiest to clean—the most profitable in every way. We have a book that tells you why. Get it.

Empire Cream Separator Co.,
Bloomfield, N. J.
Western Office, FISHER BUILDING, CHICAGO.

Notice to Dairymen

If you are thinking of buying a Cream Separator write us for Catalogue and information. We manufacture the best machine on the market.

Davis Cream Separator Co.,
54 to 64 N. Clinton St.
CHICAGO, ILL.



Measure the Milk of each Cow

With the **Automatic Milk Scale** you can keep an accurate record of the yield of each cow, and remove the unprofitable ones from the dairy. Each button on scale arm corresponds to number of cow, and when pail of milk is weighed the button registers the weight on score card. Big money saver and money maker for farmers and dairymen. Send for testimonials and illustrated catalogue of **Bestov** dairy supplies.

WILL IT PAY YOU TO TAKE HOARD'S DAIRYMAN?

W. H. Jenkins took a census in 1901 of 50 farmers who were patrons of the creamery in Montrose, Pa. Twenty-five of themread dairy papers; twenty-five did not. The twenty-five who did read dairy papers averaged $50.23 per cow for the year. The twenty-five who did not read averaged $32.95. Here is a difference of $17.28 per cow. Did it pay the twenty-five to read? Did it pay the other twenty-five not to read? That's not all. Those who did read averaged a profit over cost of food of $15.06 per cow. Those who did not read averaged a profit of 66 cents. Is not that dairy farmer standing greatly in his own light who will not pay 2 cents a week for Hoard's Dairyman? These are hard facts worth thinking over.

MILK RECORD BLANKS.

In compliance with numerous requests, HOARD'S DAIRYMAN has prepared two kinds of Milk Record blanks. Each blank has spaces for entering the morning and evening yield of milk for thirty-one days, and differ only in that the larger blank suffices for ten cows, while the smaller one is intended for only one cow, but has a column for the per cent of fat and a wide space for remarks. These blanks are printed on heavy manilla paper, are furnished at only a slight advance on bare cost, and should be faithfully used in every stable, for in no other way can the dairyman know with any degree of certainty which of his cows return him a profit and its amount, and which are kept at a loss and its amount.

See the Business Department's advertisement of these blanks in another column, and order at least enough to give a fair trial of their usefulness.

THAT is a rare compliment Mr. Geo. Hail pays the DAIRYMAN in his silo inquiry in another column, when he says: "It so completely covers the whole business that a man only has to read it carefully a short while and he gets all the information wanted."

PROF. HAECKER requests us to announce that copies of bulletins 67 and 79 can be obtained free by applying to the Minnesota Experiment Station, St. Anthony's Park, Minn.

SINCE 1884 the amount of milk shipped into New York City has increased three-hundred per cent. We are certain that neither the increase of population nor of cows, is within two-hundred and fifty per cent of that figure. What is true of New York, is true also, of all other cities and villages of the country, to a certain extent. These facts ought to convince the dairy farmers of the land, that there is a good busines ahead of them in raising dairy cows from specifically bred dairy sires.

THE name of T. S. Cooper is so indellibly linked with American Jersey interests that it seems almost a work of supererogation to call attention to his forthcoming sale of imported Jerseys at Linden Grove, May 30th. It is entirely safe to predict a large and enthusiastic attendance of Jersey breeders on that occasion, and that there will be spirited contests for the possession of some of the specially fashionable animals, but if this sale follows the precedents established at previous Cooper sales, much the larger proportion of the animals will sell well within the limits of actual value to breeders who are not millionaires or the sons of millionaires, and have no money to invest simply to gratify personal ambition or pride. The Case and Walker Sale, to which reference is made elsewhere amply justifies this forecast, and should be an encouragement, not alone for professional breeders, but for progressive dairymen to attend this sale. Indeed it will be time and money well spent to attend, even though no purchase be made or contemplated. It will be a liberal education in animal husbandry just to see such a collection of the best animals the Island of Jersey can turn out.

There are two kinds of value in dairy cows. One is ability to produce profitably at the pail, and in this respect the dairy cow occasionally has a not unworthy rival among general-purpose animals, and even among the strictly beef breeds. Although this is a value not to be lightly considered, it is of vastly less importance than the ability to transmit dairy capacity to her offspring, whether in the strictly dairy herd or in the herds of professional breeders. Not all dairy-bred cows have this ability, and so far as the records show none of the general-purpose or beef animals have exhibited ability of this character. This ability is very properly termed prepotency (overpotency) because the sire or dam possessing it appears to have a preponderating influence upon the offspring. It is also a transmissible quality.

It is because of these facts that we urge breeders and dairymen to attend such sales as, for example, that of Averill & Gregory at Syracuse, June 4th and 5th, where such animals as A. & G. Butter King (whose first three daughters are going into the Holstein Advanced Registry), and Segis Inka (with a record of over 20 lbs. butter in seven days and a daughter better than herself), are to be offered. These are but samples of the meritorious animals in the justly celebrated A. & G. Herd.

CANNED CHEESE CURD.

Prof. Pernut, of the Oregon Experiment Station, has made some very interesting experiments in taking fresh cheese curd ready for the press and sealing it hermetically in tin cans. In this condition the curd goes through the curing process in good shape. The cans holding about five pounds were first paraffined, the curd was then packed in the tins under pressure remaining in the press over night. They were then soldered and laid away. The loss of the rind and a large per cent of the usual shrinkage was thus avoided. Who can tell but what this may open the door to a new method of putting up cheese for market?

WHY BREEDERS DO NOT EXHIBIT THEIR CATTLE MORE.

Secretary Caldwell in the last Guernsey Herd Register discusses briefly the reason why so many Guernsey Breeders do not exhibit their cattle at fairs. There are two reasons which he does not state: Dairy cattle are much more sensitive to change than beef cattle. To make a good impression a dairy cow must be in full flow of milk. If she is in that condition to take her to a fair is almost always sure to injure her for that season at least. Then again with bulls, the foolish demand of the show ring is that the animal must be in a show condition. He must be fat and in a condition which is diametrically opposed to his usefulness as a breeding animal. Mr. Wallace, one of the leading breeders of Ayrshires, in Scotland, refuses to exhibit his cattle at fairs.

A few years ago he wrote us that his reasons for this action were that the judges demanded that show animals be fitted for exhibition in a manner and condition which utterly unfitted them for their chosen work. He could not exhibit his animals, and have them judged on their merits as dairy cattle. Therefore he chose not to exhibit. We have frequently seen a Shropshire buck so fitted for exhibition that the owner would confess that he was worth nothing as a breeder. While animal judging is kept on this senseless line, owners of fine dairy cattle will feel loth to place them on exhibition, even if such showing would prove of great advertising value.

ODDS AND ENDS.

Judging from letters received, there is a very large amount of "want to know" concerning the amount of fat in milk and cream, among dairymen. This is no new condition, only it seems to be more widespread than formerly and the want to know is much more decided in its character. It also seems that the average dairyman is always a "bull" on the richness of his products. So long as the per cent stays up there is no complaint, but let it go down and there is at once a want to know feeling, which is expressed to the buttermaker, the neighbors and in some cases to the DAIRYMAN. The question is usually expressed about as follows: My test in milk, or cream, last month was ——; this month it is so much lower. Why should it be thus? My cows are the same, no change in feed, care, separator, cream screw, wind, water, or distance to factory.

It is difficult to educate dairymen into the fact that both milk and cream vary widely in fat content, and that for no reasons that can be given as satisfactory. No cow can be kept in such regular conditions as to food, drink and surroundings, that the composition of the milk will not change from day to day and from hour to hour. The action of the nervous system of the cow is beyond measurement by any instrument possessed by the Experiment Station and until such an instrument is invented, the reason why a cow gives 4.5 per cent milk Monday and 3.5 per cent milk Tuesday, will be beyond explanation. The men who buy sugar beets trust nothing to the theory of averages, they sample and analyze every load of beets; the man who mines gold also samples and analyses, but the man who produces milk trusts to averages and only kicks when he finds his returns sometimes below the point that he considers proper.

If the milk is a variable quantity, the cream must necessarily follow. The separator, although a powerful machine, is limited in its action. It will remove all the fat, but the amount of skim milk that comes along with the fat varies. It may be more or less according to the different conditions that affect the separation—the rapidity with which the milk is fed, the temperature of the same, the amount of fat it contains, etc. No dairyman can make these conditions so uniform and unvarying that the per cent of fat in the cream will not change with every mess of milk separated. The change may be but slight, or it may be considerable in amount and the butter maker is not to blame if your cream tests 20% fat this week against 25% the last week in March. If you don't believe it, make a few experiments with separator and Babcock test, and you may be convinced even against your own will.

There are many things connected with the dairy that cannot be brought down to exact figures and one of them is the exact or approximate value of a cow. What is a cow worth, is a never ending question because of the unknown qualities which enter into her make up. In the first place, the cow is a machine and as such she always has a certain value. Her foundation price may be anywhere from $25 to $50, according to her weight and the price of old cow for canning or bologna. The question is as to how much value must be added to the above to obtain her actual value. It is safe to assume that the yearly net profit enters into this question. If the cow returns to her owner a net profit of $10 over and above all expenses, the cow is worth to him $10 over her value as a beef producing animal. So if we want to put the above in a formula, we can say that the average cow is worth her beef value plus her yearly net profit, or she is worth her own live weight plus her owner's ability as a dairyman as shown in net profits. The best Jersey or Holstein that ever lived would be worth but their live weight in the hands of some men, while a scrub would be worth twice the value of the pure bred dairy cow if it was in the hands of a skilled feeder and dairyman.

So it seems to be a question of what is the cow value of a dairyman as well as the cash value of a cow.

Some time since the scientists informed us that the keeping of silage depended on the intramolecular respiration of the cut cells of the corn, which used up the oxygen of the air, caused a decided increase of temperature with consequent conditions for producing silage of good quality. But once in so often the practical silo man comes along and "wants to know" why his silage don't keep, has spots of mold around the sides or in the center. It is of not much use to tell him that the intramolecular respiration is insufficient for the proper formation of the silage, and we have to fall back on results from practical work which indicate that corn, as is frequently the case, when left to mature much beyond the glazing state of the kernel, contains a much smaller amount of water than when it is cut at the proper time. The result is that there is enough water left in the corn to grow mold and not enough to soften the cut corn so that it will pack solid and keep out the air. The remedy for such conditions is to add water during cutting. This softens the hard, partly dry corn and the mass packs better, with much less liability of mold.

When the universal tendency is toward simplifying weights and measures it seems like advancing backwards to make any change in our present system unless it be towards simplicity. The Minnesota Legislature, for reasons best known to itself, passed a law last winter providing that milk measures should be based on a gallon of 282 cubic inches. There is at present the dry measure gallon of 268.8 cubic inches; the liquid measure gallon of 231 cubic inches, and to make confusion worse confounded, Minnesota now has one of 282 cubic inches. It would be interesting to know the reasoning and facts on which this new gallon was established. There must have been something else besides the fact that Queen Elizabeth constructed a standard gallon of 282 cubic inches, for that does not seem sufficient to tip over the present standard, and modern Minnesota is a long distance from Queen Elizabeth. If it had been attempted to establish a metric gallon of 244 cubic inches there would have been some reason in the change, but we can see no rhyme or reason for the change in the size of the Minnesota gallon. F. G. S.

Sorghum Silage.—Milk Fever.

ED. HOARD'S DAIRYMAN:—On page 310 I saw an article on sorghum silage from H. B. Cowles. Last year I planted a few acres of sorghum seed with corn, half and half. When corn was right for silage the sorghum was all headed out. I was delighted with the big yield. I cut it with binder and let it wilt for two days. Having two silos it came so that each silo had its share of same, having all corn below and also on top of it.

As soon as I came to the mixed silage the cows did not like it near as well, although it looked perfect, only smelling more sour. I had quite a shrinkage of milk which lasted till I came to the full corn silage again. It turned out just the same in my second silo.

Now, it may have been all my fault, but reading Mr. Cowles' experience I think I had better leave sorghum alone for silage.

Those articles on the manure question were very interesting, but today I am more than ever pleased to have all the manure away in the pasture and field, drawing it away every day except Sundays. I think those men who are afraid for a rain on their manure had better never distribute same on the ground as those rains will come any time. We are having a terrible rain here today which takes away more of my manure in the pasture than it did all winter. Had I all manure in the yard there would be no chance to haul it now. We have a Drew elevated carrier running over a 120-feet long wire, dumping the manure on the wagon box. It works very easy, but the manufacturers should provide a seat so a fellow could ride back into the barn as it runs much faster than a man can walk.

I have lost four cows now in three years' time from what you call *Parturient Paresis* (milk fever). With my two last ones have applied the Schmidt treatment, following the directions. They both got up again, but died in spite of it. They both kept up a constant moaning and drumming sound on their lungs. By removing the contents of the rectum found with both these cows much blood, which our veterinary said is a fatal sign. Examining the cows inside after death found the upper parts of the lungs dark and bloody, and by opening the small round stomach the linings peeled off with little food in same, could find nothing wrong on anything else. Now, if the Schmidt treatment got those cows on their feet so they could walk easily, why did those cows die? D. J. DEH.

Boyden, Ia.

Since your cows came to their feet, as would be expected with the Schmidt treatment, it was your duty to watch the heart action, which is very much affected during and after an attack of this disease. When the heart becomes feeble it must be stimulated with an occasional dose of aromatic spirits of ammonia, say ½ to 1 ounce at a dose, or you may choose some of the other heart stimulants.

The condition of the lungs after death was such as are usually found on post mortem examinations and have nothing to do with this case. Bleeding from the rectum is caused by introducing the hand into the organ and rupturing blood-vessels.

Changes in Cream Quality.

ED. HOARD'S DAIRYMAN: — Will you tell me if milk from green grass or milk from fresh cows has any influence on the hand separator. The cream test this spring is much lower than it was in the winter and fall months. The patrons say they have not changed their separators.

I have two patrons whose cream test was twenty-nine and thirty when their cows were nearly dry; now they have some thirty fresh cows and now their test is twenty and twenty-two. Can you tell why it should vary so?

I use M. Preserveline to keep my sample. Is there anything better?

I use the Babcock test. Weigh 18 grams cream for the test; run the machine nine hundred to a thousand revolutions per minute. The fat column is clear. Is my test correct? E. A. T.

Elizabeth, Colo.

It is not surprising that the cream test varies; the surprise would be if it did not vary. Milk is not a constant body. It is subject to changes in composition, quality and physical condition and as the milk varies and the conditions of separation also vary it is not possible to obtain cream that does not fluctuate in the per cent of butter fat. The only proper method is to test each batch of cream, do it properly and accept the test as being correct. The fable that cream is cream and that so many inches will make a pound of butter has ruined many creamerymen.

DON'T PUT OFF

Seeing your friends and having them join in for a good club of subscribers.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

Thick Shoulders.

I purchased a Holstein bull calf 2 years ago that has all good dairy signs except so wide across the shoulders. Do you think it will spoil him as a breeder? His heifer calves are all the same over the shoulders.

HOARD'S DAIRYMAN has done me stacks of good in dairying. My neighbors begin to notice it as you see by the names on the subscription blank herewith. F. J. S.

Saginaw, Mich.

Animals perfect in every respect are not very abundant, and more frequently than otherwise perhaps, we have to balance the good points against the defective ones. We should much prefer, at the head of our herd, a sire with comparatively sharp withers but should not peremptorily discard one for this defect alone, if his pedigree, and especially the performances of his ancestors were satisfactory. The present writer, disagreeing in this respect with a good many excellent judges of dairy cattle, places most emphasis upon the build and contour of the hind quarters. Given a large deep middle piece for the storage and digestion of raw material, we like to have thin, incurving hind quarters as these are conditions precedent for affording room for a capacious udder. As a rule, nature does not provide these thin incurving thighs unless there is to be a milk vessel to fit the place. It will not be very long now before these heifers will be coming in milk and then, and not until then, can it be determined with any degree of certainly whether the sire is what he should be or not.

Thanks for the list of new subscribers.

Information about Beans as Food for Stock Wanted.

Can you furnish us with any book or pamphlet that will give the analysis of beans and their value as feed for all kinds of stock and poultry as compared with other kinds of feed?

We are interested in feeds and feeding as we expect to put a special brand of feed on the market soon. We also intend putting out a stock food, which we are now working up and perfecting. If you have anything to offer that will assist us, please let us hear from you. R. & Co.

Nunda, N. Y.

We do not know of any book or pamphlet which treats of the relative feeding value of beans as a feed for stock. We have a memorandum, but without reference to the source from which it was obtained, to the effect that beans contain 85.5 per cent dry matter, including 23 per cent of digestible protein, 50.2 digestible carbohydrates and 1.4 ether extract. We do not think that beans have been much used as a feed for stock in this country and there is some question as to whether they would make a really palatable food.

Compressed Air Sprayers.—Best Grain on Pasture.—Selling Milk or Making Butter.

Please let me know if there is a compressed air sprayer on the market that will spray the oils used on cattle to exterminate flies. If there is, please to give me the manufacturers name and address. What do they use in the large dairies, where they have 100 cows or more, both for liquid and sprayer to apply it with. I have 20 cows and find it quite a job to spray that many and do it thoroughly every morning.

What is the best grain to feed cows on pastures, at the following prices: Bran, $1.25 per cwt.; Daisy flour, $1.40; Biles XXXX distillery grain, $1.50, 33 per cent protein; corn meal, $1.15; cotton seed meal, $1.65, 43 per cent protein; linseed meal, $1.60; oats, 50 cents a bushel?

Which would you consider the most profit in, selling milk at 3 cents a quart, wholesale, 2 miles to take it to station, or make butter where it sells for 20 cents?

Would you think it any use to try alfalfa here in Eastern Maine, on a small scale?

Do you think that the 2 and 4 bottle Babcock testers will do as good work as the larger ones? I am about to buy one and a 4 bottle will do me if it is of practicable size. J. T. M.

La Grange, Me.

We do not know that there is any sprayer working with compressed air that would answer the purposes of our correspondent. There are several such sprayers for white-washing interiors and exteriors of buildings, but we should think them perhaps too cumbersome for use in spraying cattle. However, this is a proposition that appeals to the manufacturers of these machines and indicates that they might profitably use our advertising columns.

For a discussion of the most appropriate grain to feed to cows when on pasture, see the answer to H. S. W., of Otter Lake, Michigan, on page 319, ante.

Whether it would be more profitable to sell milk at three cents a quart or make butter at 20 cents per pound, would depend upon the quality of the milk sold. One hundred pounds of milk is equivalent to forty-six and one-half quarts which at 3 cents a quart would come to $1 39½. If this milk tested 4.3 per cent fat, one hundred pounds of it would make five lbs. of standard commercial butter, which at 20 cents a pound would come to $1.00. In addition, one would have the skim milk, worth at least twenty-five cents for feeding purposes alone, and from seven to twelve cents additional for fertilizing properties.

This matter of available fertility in different feed stuffs is not as much considered as it should be by the practical farmer and dairyman. At the last winter's convention of the Dairymen's Association of Eastern Ontario, Mr. J. W. Hart, Superintendent of the Kingston Dairy School, read a paper on butter making, in which he included a table showing the fertilizing ingredients removed from the soil in selling milk, as compared with the sale of cheese and butter. Nitrogen was valued at sixteen and one-half cents, phosphoric acid at 5 cents and potash at 5 cents per pound. We copy that table as follows:

PRODUCT	*Nitrogen lb.*	*Phosphoric acid lb.*	*Potash lb.*	*Value*
25 tons milk	265	95	90	$52.97
2½ tons cheese	196.5	30	6	24.22
1 ton butter	2 4	0.8	0.8	.47

It appears from this table that when one sells butter, he is conserving the fertility of his soil (if he takes proper care of the manure) but when he sells milk or cheese, he is drawing heavily on the soil fertility needed for succeeding crops. We are of the opinion, therefore, that in the long run, it would be decidedly more profitable to make butter at 20 cents per pound than to sell milk, testing over four per cent, at three cents a quart.

There is no reason why a small Babcock test should not do just as good work as a larger size if operated according to directions.

It is well worth while to try alfalfa, but at first on a limited area, say one acre.

Condensing Factory Offers Large Price for Milk.

There is a movement on foot here to open a condensed milk factory, the price they offer (35 cents per lb. for butter fat) being about 40 per cent higher than the cheese factories, and 45 per cent higher than the creameries have paid during the past two years. They offer to contract at the above price for five years. Would you advise the dairymen of this locality to enter into such a contract and allow the co-operative cheese factories and creameries, of which there are four, to discontinue making?

Thirty five cents is certainly a fancy price for butter fat, but it may be the death of competition in which case we may in a few years have to accept a great deal less. D. F.

Tillamook, Ore.

An increase of forty per cent over present prices is, of course, a very tempting propositon and one which in some respects should occasion some suspicion. It would seem to be hardly necessary for a new concern to go into a neighborhood and offer that much advance. However, if the company is responsible and can offer proper assurance that they will carry out their contract in good faith for five years and do not ask any bonus or other contribution towards the establishment of their plant, one could hardly blame milk producers for entertaining the proposition with considerable favor. However, questions of this character are not altogether proper ones to submit to others. Business propositions should be decided by each man for himself and the people in this community are quite as competent as we, or others, can be, to foretell what course this condensing factory would be liable to take at the expiration of their five years' contract. In the nature of things, they could not be expected to pay more for milk than could be conveniently obtained for it elsewhere or for other purposes.

Time to Plant Silo Corn.

A. B., of Lancaster Co., Pa., asks whether May 20th would be a good time to plant silo corn, how much seed he should use per acre and how many acres he should plant for twenty-five cows?

As stated in last week's issue, we should expect to get a good yield of corn in this climate from properly prepared soil if planted as late as the 10th of June, but should much prefer, of course, to plant a month earlier if the season permitted. We are writing this answer on the 15th of May and, as far as we are advised, not an acre of corn has been planted as yet in this vicinity. The amount of seed to use per acre will depend somewhat upon circumstances. We usually plant from one-quarter to one-third more seed for silo corn than we would for a crop to be harvested for grain. It is usually a safe estimate to expect from ten to twelve tons of silage per acre, and, for winter purposes alone, we like to provide about three tons for each cow.

The Alderney Cow.

Mr. Walter R. Cuthbert, of Philadelphia, is anxious for some information on the Alderney cow. Why there are none to be seen catalogued at fairs? Whether there are any in this country? What the laws of the island of Alderney are in regard to exportation and so forth?

Formerly, both in England and America, all Channel Island cattle were called Alderneys, but why so called has never been satisfactorily explained, as the island of Alderney is much smaller than either Jersey or Guernsey. There is much similarity in the cattle on all these islands, but those on Alderney more closely resemble Guernseys than Jerseys, in color and markings. Following the English precedent, the first importations of Channel Island cattle into America were termed Alderneys, but upon the organization of Herd Register for these animals in 1868 the name Jersey was substituted. Later, when the importation of animals from the Island of Guernsey became more frequent the Guernsey Cattle Club was organized, and between the two not only has the name Alderney disappeared, but also, so far as we are advised, no importations have been made from the smaller island.

Locust Seeds.

Please inform me where I can get the seed of the yellow locust, the kind used for fence posts. Some say it is black locust. P. H. F.

Richland Center, Wis.

We do not know that locust seed has anywhere become an article of commerce. Probably the only way at present to obtain seed would be to visit places where locust trees are growing and gather them personally, or to advertise for them.

It would undoubtedly pay farmers a good profit, at present and prospective prices for fence posts, to devote a corner somewhere to grow locust trees for posts, and according to information furnished by the cyclopedia, it does not much matter what variety is selected, although the apparent preference is given to the so-called black locust.

Two Silos for Forty Cows.

I wish to build two silos ten or twelve feet in diameter for forty cows, how deep should they be? I usually find all I want to know answered in the DAIRYMAN by watching for a month or two, without bothering you with questions; but this time I have overlooked it. This is the second time I have had to ask a question during the twelve years I have been taking the paper. It so completely covers the whole business that a man only has to read it carefully a short while and he gets all the information wanted. GEO. HAIL.

Chepultepec, Ala.

The amount of silage required by forty cows will depend upon the amount fed per day, and the number of days it is to be fed. In this latitude, the careful dairyman estimates for feeding 200 days at least, and at the rate of not less than an average of 30 lbs, per day to each animal. More and more, also, is he beginning to provide some extra for use during the summer drouth, and does not consider four tons per cow any too much for a year's supply.

We would advise our friend not to build any thing less than 12 feet in diameter and 20 feet in depth. Such a silo will hold approximately 37 tons, or if filled a second time after settling a few days, say 40 tons. If he gives his silo 25 feet depth, its capacity will be increased fully 30 per cent, or to 51 and 56 tons. A silo 12 feet in diameter and 30 feet deep will have a capacity, if filled the second time, of about 75 tons.

If at all practicable, the bottom of the silo should be about 4 feet below the level of the feeding floor in the stable.

Herd Records in Illinois.

Report of Herd "A".

ED. HOARD'S DAIRYMAN:—Herd "A" was composed of natives, grade Shorthorns, grade Jerseys and grade Holsteins. The average weight of each cow was about 1,000 lbs. The herd on the whole was not bred for dairy purposes, moreover, they neither showed dairy form nor capabilities of giving large flows of milk, or producing large amount of butter fat. Nearly every cow showed some signs of disorder. They were not in thrifty condition. A number of them aborted during the year, while others failed to get with calf, and were sold. Some of them were disposed of so early in the test that their records are not calculated with the rest of the herd.

There were also ten other cows kept in the herd whose milk was not weighed or tested. I am sorry that the owner could not see the importance of weighing and testing each one of these cows, but the average amount of milk and butter fat that each of the untested cows produced for the year will be given; for a record of the amount of milk and butter fat that was sold from all the cows was kept. The herd did not yield the amount of milk and butter fat that it should for the amount of grain and roughage each cow ate, to be reported upon. He fed, however, a ration to his cows that was largely made up of corn and other foods rich in carbohydrates and containing a small per cent of protein. The cows received a small allowance of bran with the corn meal from October 1st, to January 1st, During the months of January and February, to the cows giving the largest flows of milk was given the following ration:

FOOD STUFFS.	Lbs.	Dry Matter.	Protein.	Carbo-hydrates.	Fat.	Cost.
						Cents
Corn meal.....	10	8.91	.790	6.670	4.30	10
Silage.....	35	7.31	.315	3.955	245	3.5
Timothy hay.....	10	8.68	.280	4.34	.140	5
Total nutrients		24.90	1.385	14.965	.815	18.5

This ration is altogether too rich in carbohydrates and contains a very low per cent of protein. If this farmer had sold more of his corn and bought some mill feed, he would, with less expense, have improved the ration. For example, a ton of corn meal at this time would have paid for more than a ton of grano gluten. If a ration is made from 5 lbs. of grano gluten and 3 lbs. of corn meal with the same amount and kind of roughage as contained in the above ration, we will have a far better and cheaper one. This ration would contain the following nutrients:

FOOD STUFFS.	Lbs.	Dry Matter.	Protein.	Carbo-hydrates.	Fat.	Cost.
						Cents
Grano gluten...	5	4.71	1.335	1.94	.610	5

A number of the cows' udders became feverish and hard during the time that they were being fed so much corn. Four of them were giving milk from only three teats. It seems as though that excessive corn feeding must have had something to do with the general unsatisfactory condition of the herd, especially in the months of January and February, and perhaps the cause of four of them losing the use of one-quarter of their udders. The first of March, rye was added to the ration. The rye and corn meal were mixed equal parts by weight, and about eight pounds of the mixture, together with timothy hay and corn silage, was the ration they received until May 1st, when ground oats was substituted in the place of rye. The cows were turned out to pasture about the 25th of May, but were given a small allowance of silage to July 1st. From this time on to the completion of the year's work, they received nothing but grass.

The ration which the cows received from March 1st to May 1st, was somewhat better than the ration fed in January and February, but it could have been much improved with mill feed. The ration for fresh cows was about as follows:

FOOD STUFS.	Lbs.	Dry Matter.	Protein.	Carbo-hydrates.	Fat.	Cost.
Rye.....	4	3.54	.396	2.704	.044	4 c
Crushed corn and cob meal..	4	3.40	.176	2 400	.116	4 c
Silage.....	35	7.31	.315	3 955	245	3.5c
Timothy hay....	7	6.08	.196	3.038	098	3 5c
Total Nutrients		20.33	1.083	12 097	.503	15 c

It will be noticed that this ration which contains but 1.083 lbs. of protein costs nearly as much as the above ration which contains 2.167 lbs. of protein. It readily shows that by exchanging some of the home grown grain for mill stuff the ration can be made better and will cost no more, and often less. It can be said that the cows in this herd did a very ordinary year's work, but, considering the individuality of each animal in the herd, the general condition of their health together with unskillful feeding, it is not at all surprising that the results are no better.

The best cow in the herd produced 6145 lbs. of milk, 3.63 per cent fat, 233 lbs. of butter fat, and 260 lbs. of butter, while the lowest produced only 1482.6 lbs. of milk, 3 97 per cent fat, 58 lbs. of butter fat, and 68 lbs. of butter.

The average amount of product yielded by each cow tested, was 3,970 lbs. of milk, 3.55 per cent fat, 141 lbs. of butter fat, and 164 lbs. of butter.

The average production for the entire herd was 3,361 lbs. of milk, 3.55 per cent fat, 119 lbs. of butter fat, and 139 lbs. of butter.

It was found that a cow last year had to produce about 140 lbs. of butter fat to pay her board, and that the average price for butter fat when sold to the creameries was 22 cents. Calculating the results upon that basis, the cows that were tested yielded a profit of 23.1 c. To ascertain the amount of product yielded by each of the untested cows in the herd for the year, it was necessary to subtract the amount of milk and butter fat yielded by the 18 cows that were tested, from the total amount of milk and butter fat that was sold from this dairy. In this calculation a liberal amount of milk was esti-

Dr. Shoop's
Rheumatic Cure
Costs Nothing If It Fails.

Any honest person who suffers from Rheumatism is welcome to this offer.

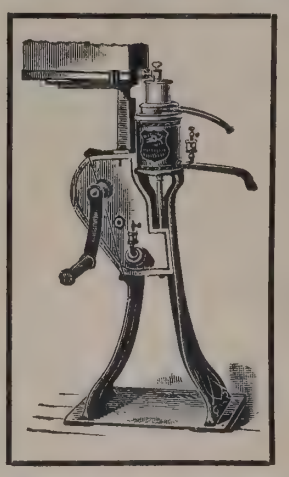
I am a specialist in Rheumatism, and have treated more cases than any other physician, I think. For 16 years I made 2000 experiments with different drugs, testing all known remedies while searching the world for something better. Nine years ago I found a costly chemical in Germany which, with my previous discoveries, gives me a certain cure.

I don't mean that it can turn bony joints into flesh again; but it can cure the disease at any stage, completely and forever. I have done it fully 100,000 times.

I know this so well that I will furnish my remedy on trial. Simply write me a postal for my book on Rheumatism, and I will mail you an order on your druggist for six bottles Dr. Shoop's Rheumatic Cure. Take it for a month at my risk. If it succeeds, the cost is only $5.50. If it fails, I will pay the druggist myself—and your mere word shall decide it.

I mean that exactly. If you say the results are not what I claim, I don't expect a penny from you.

I have no samples. Any mere sample that can affect chronic Rheumatism must be drugged to the verge of danger. I use no such drugs, and it is folly to take them. You must get the disease out of the blood.



My remedy does that even in the most difficult, obstinate cases. It has cured the oldest cases that I ever met. And in all my experience—in all my 2000 tests—I never found another remedy that would cure one chronic case in ten.

Write me and I will send you the order. Try my remedy for a month, as it can't harm you any way. If it fails it is free.

Address Dr. Shoop, Box 934, Racine, Wis.

Mild cases, not chronic, are often cured by one or two bottles. At all druggists.

IS THE BUTTER YOU EAT
MADE FROM CREAM SEPARATED BY A
U. S. SEPARATOR?

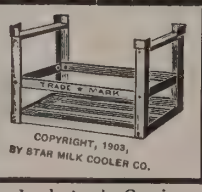
IF NOT, YOU SHOULD SEE THAT IT IS.

In buying butter or cream, always ask if the milk was run through an Improved U. S. Cream Separator. If it was not, you may be sure the product is not as good as it might be, for it

Takes the Best to Make the Best.

and it has been proved many times that

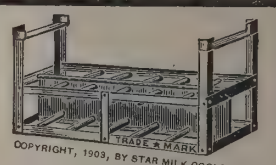
THE U. S. SEPARATOR EXCELS ALL OTHERS.



At the Pan-American Model Dairy it
Won WORLD'S RECORD for Clean Skimming.

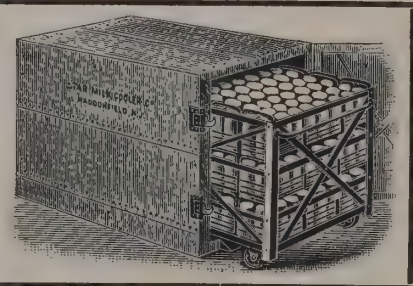
For further particulars write for illustrated catalogues.

For Western customers, we transfer our separators from Chicago, LaCrosse, Minneapolis, Sioux City and Omaha. Address all letters to Bellows Falls, Vt.



Vermont Farm Machine Co.,
BELLOWS FALLS, VT.

WHEN YOU SEND IN YOUR RENEWAL, SPEAK TO A FEW OF YOUR NEIGHBORS AND HAVE THEM JOIN YOU. CLUB RATES: 2 Subscriptions, $1.50; 3 Subscriptions, $2.00; 4 Subscriptions, $2.50; 5 Subscriptions, $3.00.



Lock Angle Carrier.

Star Sterilizing Apparatus

Will assist the keeping conditions of milk by thoroughly cleansing Utensils, Bottles, Cans, Etc. This is the Star Carrier showing Spacer, an absolute necessity in Dairies making any pretentions towards supplying milk hygienically. Write for STERILIZER BOOKLET which will give you full information in regard to Sterilizing Apparatus.

Star Spacer.

STAR MILK COOLER CO., Haddonfield, N. J.

EASY. It is easy to go on losing money by taking care of milk in the old way, that is, by not taking care of it: But it is easy, too, to take proper care of your milk with a

Champion Milk Cooler-Aerator

The Champion is pre-eminently the easy Cooler—easy to buy, easy to take care of, easy to use.

mated for house use and for the feeding of calves.

Total amount of milk sold from Farm "A"	97721.0 lbs.
Total amount of milk yielded by tested cows	76060.9 "
Total amount of milk yielded by the 10 untested cows	21660.1 "
Average amount of milk yielded by each untested cow	2166.01 "
Total amount of butter fat sold from Farm "A"	3554.43 "
Total amount of butter yielded by tested cows	2751.47 "
Total amount of butter yielded by 10 untested cows	803.01 "
Average amount of butter fat yielded by each cow untested	80.30 "

Calculating the whole herd together, and estimating that it takes 140 lbs. of butter fat to pay for a cow's board, there is a loss of $4.54 per cow, or each cow should have produced 20.64 lbs. more butter fat to have paid for her keeping.

The best cow in this herd gave a profit of $18.40, and the poorest one charged $17.83 for her board.

Table giving the list of cows in herd "A" with age, breed, date of calving and days in milk together with the amount of milk, the per cent fat, the amount of butter fat and butter produced by each cow in the herd, beginning Sept. 24th, 1901, and ending Sept. 24th, 1902.

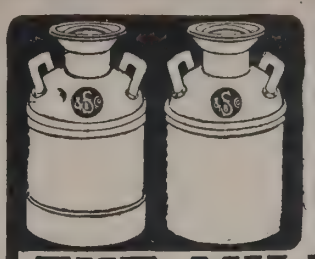
Elgin, Ill. A. J. GLOVER.

Ravages of the Alfalfa Cutworm.

The insect doing so much injury to growing crops of all kinds, particularly to alfalfa and spring grain is a true cutworm. Because of its habit of appearing in enormous numbers on occasional years and taking on the army-worm habit of migrating into fields it has been called the army cut-worm The insect is a native of Colorado, its natural food-plants being chiefly the wild grasses. The worst injuries I have seen have been to crops growing next to the land that has never been cultivated, or to crops on new ground that was plowed for the first time this spring. I have just returned from a field of barley on virgin soil recently plowed and where the barley was making a good showing a week ago. Now every blade is eaten down to a depth of an inch or more beneath the surface of the ground.

These worms may be expected to continue their depredations until about the middle of May or a little latter. They will then change to dark colored chrysalids in the ground and about the first of June will change to dark-colored moths, or millers which will fly into our houses and become a nuisance upon the windows and about the lights in the evenings, as they did last June. These moths deposit eggs in the fields that produce another crop of worms in August and a second brood of moths in September. The September moths lay eggs again which soon hatch into little cut-worms that become only partly grown in the fall and which hibernate in the ground until vegetation starts in the spring when they come to the surface very hungry from their long fast and then attract attention, if very numerous, because of serious damage to young growing plants.



When the worms are found marching into a field along the border, a ditch of water that has a good current and that is eighteen inches across will make a fairly effectual barrier. Better than the ditch is to thoroughly poison the crop upon which the worms are feeding just in front of the line of march and along the line wherever they are found feeding. Use the arsenites such as Paris green or London purple, in the proportion of a pound to 100 gallons of water or mix one of these poisions with common flour in the proportion of one to twenty by weight and dust the mixture on the food-plants in the early morning where there is dew enough to make it stick. If the ditch of water is used, the poison should also be placed on the side of the ditch next the worms. When the worms occur over an entire field, there is little to do but to wait for them to mature, probably about May 20th, and then put in some crop that can be raised after that date.—F. C. GILLETTE in *Field and Farm.*

Wants a Good Holstein Bull.

I have a herd of 23 cows; am wholesaling my milk, ship to Joplin, Mo. Commenced keeping record of herd Oct 20th, last year. Will report when year is up. Have a mixed lot of cows but about all of them are the best that can be bought here. I want to buy a thorough bred Holstein bull. Would you advise a man with limited means who wants a good bull to buy a calf or an old one? I know of none close to me. A. Mc. K

Varck, Kans.

If at all practicable by correspondence or personal investigation to secure a satisfactory bull of mature age, we do not hesitate to say that we would consider this a better investiment than to purchase a calf. There are several first-class herds of Holsteins in Missouri, in Kansas and Nebraska. Some of them advertise in the DAIRYMAN, and in our judgment, it would pay others to advertise so that people situated as Mr. Mc. K. is, may know to whom to apply for animals suited to their interests.

THE MILK CANS TO BUY.

You do not need to be told that there is a vast difference in milk cans. You can make no possible mistake if you select any one of our universally approved **Iowa, Elgin, Chicago, Burn, Omaha** or **Wisconsin** patterns. Made of steel with strong protecting bands, they are the best guarded against denting, and their loaded or soldered inside seams, with heavy tinning and retinning, make them easy to clean and leave no chance for rust to start. In the superior shapes of their non-pull-off handles, they are not approached by any other make. Ours is

A CREAMERY SUPPLY HOUSE

not connected with any trust. In addition to a general line of creamery machinery and milk dealer's supplies, we manufacture such specialties as the **Dairy Queen Churn, Boyd Cream Ripener, Cream and Milk Vats, etc.** If you wish to build a combined butter factory on the co-operative and separator system, write us, and we will send a competent man to organize the company for you. We equip them on strictly sanitary lines, for which our improved appliances are noted. We publish a special appropriate catalog for every specialty and for every branch of our business. Write us for anything in the creamery supply line and we will mail free the proper catalogue.

STURGES & BURN MFG. COMPANY,
Kansas City, Mo. Chicago, Ill. St. Paul, Minn.

Truth to Tell

There are no other milk cans made that can equal in wearing qualities the genuine

BUHL CANS

They are tinned to stay tinned, and put together to stand years of hard service. Other cans crack easily, become dented, and being lightly tinned soon rust and go to pieces. Not so with the "Buhl Factory," "Improved Elgin" and "Genuine Iowa." They will outlast any other cans on the market, and are thoroughly and quickly cleaned, **Remember,** the Buhl is the only can in the world that is made with the **Buhl "Victor" Can Breast** and the **Buhl "Victor" Round Handle.** As there are many inferior imitations of this can, we stamp all ours with the **Milk Can Trade Mark.** Look for it. Sold by all live dealers. Ask about them, or write us direct.

BUHL STAMPING COMPANY,
212 W. Larned St., Detroit, Michigan.

GOOD BUTTER
Brings Good Prices,

if it gets in the right market channel. We have superior facilities for getting best figures on **fine hand separator butter.** Trial shipment asked. We post you on market.
C. H. WEAVER & CO., 128 S. Water Street, Chicago.

Creasey Ice Breakers

Dairymen and shippers of milk and cream find them most efficient, economical machines, and the greatest savers of time and ice. Easy to operate. Rapid cutters. The design is right. Made in sixteen sizes to suit every requirement. Send for catalogue "11-B" which gives full particulars.

J. S. L. WHARTON, Mfr.,
17th & Clearfield Sts. Philadelphia, Pa.

The Distribution of Skim Milk.....

It is known that the just complaints of creamery patrons on account of unfair distribution of skim milk are the bane of the separator creamery business. Further disputes among patrons, annoyances to managers, hindrances to the best work of buttermakers, watering the skim milk, and many other ills in the same train are unnecessary, since the

Barber-Coleman Check Pump

has for more than five years been successfully solving the problem in many different creameries. When a patron has dropped in his check he can pump the amount of skim milk called for by his check, less the percentage taken out as cream, so in like proportion to all other checks. Its measuring apparatus is just an ordinary pump which everyone understands and knows how to operate.

Notes from New York.

Seeding—Preparing the Seed Bed—Sowing the Grain—Turning the Cows to Pasture —Washing the Separator.

ED. HOARD'S DAIRYMAN:—So many important questions come to us at this season, the first week in May, we hardly can determine which to write of first. The question of seeding and preparing the seed bed is one that we hardly ever hear discussed through the columns of the DAIRYMAN. It is generally supposed that every farmer knows how, but a little discussion on this point may be of general interest to all. We begin the preparation of the soil the fall before by ploughing the furrows so that they overlap each other like clapboards on the house, making the lands each five paces wide with a good clean dead furrow between.

We also make cross furrows where needed so that no water can stand in depressions anywhere. This all tends to let the frost loosen and mellow and at the same time giving the harrows a chance to dig and cut on those upturned projecting edges of the furrows.

Then in the spring, we go over the land again to see that those furrows are clear, that they haven't become filled, as soon as the snow is gone. We consider this the most important part of soil preparation on our heavy clay lands, for where the water is allowed to stand through the winter and dry up with the sun it becomes baked over on the surface and sticky underneath, so that a perfect seed bed cannot be prepared.

Now when the soil has become ready for the harrow, we begin, first, by going lengthwise of the lands, then crossways, over lapping or not as required. We prefer the disk harrow for this, but sometimes we use a spading harrow when the disk does not take hold rank enough. We then finish by going lengthways with a spring tooth harrow. How deep do you work the soil? We work until we have it plenty and mellow. We let the spring tooth run on old land as deep as it will and not jump and on sod, or first ploughing, as deep as we can and not tear up the sod.

We prefer to sow our grain with a drill, as it puts the seed down to damp soil and insures a uniform germination. Then again, we can regulate the quantity of seed per acre; we sow only two bushels of oats to the acre. Where we put on grass seed, we don't like a too heavy stand of oats where we expect to cut hay another year, as the oats rob the young clover and timothy of moisture and many times kill it. Many dairy farmers cut their oats when in the milk stage and cure it for hay. I think it is a good plan, yet we do not follow it, as we generally have more hay that gets damaged more or less and injures it for shipping, that we have to feed to our cows and horses, so we let the oats ripen and sell them after they are threshed.

Have you turned your cows out to pasture yet? We like to wait until the feed gets a good start, the weather warms up and the rains insure a plentiful supply of pasture grass for a long time to come, before we open the bars to the pasture. By present indications our cows will have to go into a short pasture this spring as we are experiencing a long period of cold, dry weather. Cows turned out early generally get the start of the feed and keep it through the summer, causing a loss the whole season through. One better buy feed on the start and keep the cows yarded a little longer than to turn them out too soon. I believe the coming pasture will be a summer silo on the larger dairy farms, rather than rely on the uncertain pasture as most of us are doing to-day.

The tramping and the soiling of the grass where the cows roam over the fields can not help but be a considerable item in the aggregate which would be entirely done away with, with the summer silo. What about the cows? Would they thrive and be healthy under that continuous method of feeding? Why not? Of course one would give them a field to exercise in. Here in New York nearly everyone has some rough land where cultivation is impossible, or would be unprofitable, that could be devoted to that purpose, while in the west where everyone has fertile fields "to burn" a reasonable range could be set aside and not missed.

Many times in writing for the papers we neglect to put in what are to us minor things, causing our writings to be misunderstood and together with the misprint and misapplication makes sorry mistakes all around. One sometimes relies too much on the ability of the readers and all the rest way down through and becomes careless about details connected with the subject he is writing up.

Of course we thought that the readers of the DAIRYMAN were familiar with bacterial growth in milk and in writing about our butter making, we tried only to give a brief outline of the work rather than submit the reasons and minute details, which we see was a mistake from the letter printed in the DAIRYMAN, page 311 of the present volume.

We stated that we washed our separator only once a day during the cold weather, assuming that the separator should be kept in a cold place where bacterial growth would not develop. We understand by our text books, cold checks such growth and only sufficient heat destroys it. Again, a separator should be washed after it has been run an hour. Whether the milk is all through or not, it should be stopped and cleaned at the end of that period to insure good results. Now then, suppose that you only have milk enough to run your separator a quarter of an hour, or a half an hour, why can not the bowl be flushed with milk at the end of that period and the rest of the run be continued in the morning.

In the meantime the machine remaining in cold storage, or, if not the whole machine, take the bowl out and put it in a cold place. Bacterial growth has been stopped and there is no more liklihood of a poor skim than as though the machine had been run a full hour at one time. I know I am right. The chemist says I am right. I know I am right. My customers say the butter is right, and it competes with, and we receive the highest retail price, in our market town where one of the best creameries in New York State is right in the corporation. We have made no little study of bacterial growth and the discovery of Pasteur, and we don't have to live in the "wild and wooly" to know when we do know a thing. We are satisfied to live in the old Empire state even if the Scandinavian pass us by.

I am reminded of the gentleman who was riding by a place and saw an Irishman beating his wife. He went in and interposed, whereupon they both set upon him and the woman, when remonstrated with, replied: "We want no interference from you, this is our fight, sor." When I again read the complaints of the dairymen from Illinois or Wisconsin, bewailing their lot because their lands don't raise in value as fast as those in the wheat and corn belt of Iowa, I shall consider it their fight. I shall ride right along and not slop ink in trying to encourage them. JAS. M. PLATO.

New York.

Dry Teat Milking.

ED. HOARD'S DAIRYMAN:—On page 273 Buff Jersey says: "When a dairyman tells me he practices dry teat milking I know he either does not milk cows or does not state facts." That is nonsense. It may or may not be possible to milk Jerseys dry handed. I don't know anything about that, but if Buff Jersey can't milk Holsteins with dry hands he is not a dairyman. We milk our cows dry handed and it's no trick at all, in fact, we can't see any advantage in wetting the teats.

I don't mean to say that the use of a little vaseline on the teats isn't good. On the contrary, I think it is a commendable way of doing, especially when the teats are chapped or sore, but to say that it is downright impossible to milk cows dry handed is a statement that I can't swallow.

And I can't believe that a little vaseline rubbed on the udder is going to keep all dirt out of the milk pail. My own experience contradicts it. A READER.

Bern, Kans.

Ear Markers.

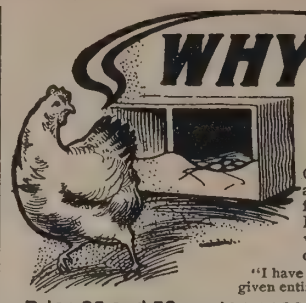
ED. HOARD'S DAIRYMAN:—After using several different kinds of ear markers without very satisfactory results owing to their getting torn out and the difficulty of reading small figures with old eyes, Beaver Meadow Farm has adopted the following plan for numbering stock which so far proves very satisfactory. Three different shaped cuts easily distinguishable are made in the edge of the ear, the shape of the cut and its position determining its number.

For instance, using the right ear for units a small slit on top stands for one, the same mark at the end of ear stands for two and on under side for three. A v shaped mark on upper side of ear stands for four, at the end for five and on under side for six, while a half circle in these positions takes the 7, 8, and 9. This provides for the units. For the tens we use the same marks in the left ear. In this way we can number to ten and the even tens to one hundred by making a single cut in one ear and all other numbers to one hundred by a single cut in each ear. After reaching one hundred make a small hole in left ear with a shoe punch or something of that sort and proceed as before.

To illustrate, a half circle in upper edge of left ear and a slit in end of right ear would read 72. A slit in top of left ear and a v in under side of right would be 16. These cuts are best made by having a punch or die which any blacksmith or ordinary mechanic can easily make, hold the ear on a block of wood and strike the punch with a hammer. This code can be varied almost indefinitely, the plan being to have three different shaped cuts that are easily distinguishable and three different positions for each. Although this was mostly all written before seeing the communication of C. H. G., Mauston, Wis., in the DAIRYMAN of April 24th, perhaps this may be of some help to him.

Mass. BEAVER MEADOW FARM.

Will Never Miss the Money.



ED. HOARD'S DAIRYMAN:—Enclosed please find $1, to renew my subscription to HOARD'S DAIRYMAN. I am a poor man, but I shall never miss the money. Your last copy is the most interesting one I have ever read. If there is any manhood in a man, the reading of HOARD'S DAIRYMAN ought to bring it out. I wish you abundant success and hope the DAIRYMAN will continue to shine on and on and on.

Disking Alfalfa.

Several experiment stations have studied the effects of cultivating the soil of a field in alfalfa. The New Jersey station has made a careful study of alfalfa culture, and in a recent publication reports

WHY SITTING HENS LEAVE THE NESTS

In nearly all cases it is because they are so pestered with lice. Of course the hen does not know that the eggs may have cost you $5 a setting—she leaves just the same. **Prussian Lice Powder** dusted freely on the nest and eggs once each ten days does the business. Does not injure the eggs, and the little chicks will be free from lice when they come out. Should you like the liquid better, don't forget our **Prussian Lice Killer.**

"I have used Prussian Lice Killer for chickens and also for horses, and same has given entire satisfaction.—RIMOND LENTZ, Jericho, Wis.

Price 25 and 50 cents per can. Remember also our famous **Prussian Poultry Food.** If your dealer does not keep any of these, write us. We will supply you and send you our **68 page book free.**

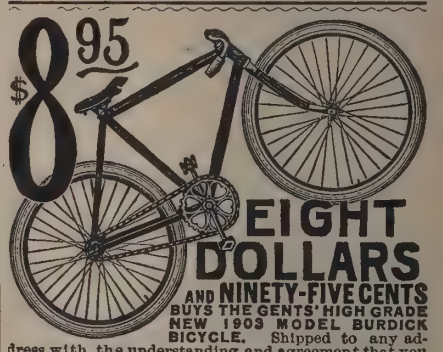
WEBER JR. Gasoline Engines

are the outgrowth of 19 years of engine building. Not approached for strength, safety, simplicity or width of duty. Valuable for a score of farm duties. Any boy can run them. 2½ full horse power at less than 5 cts per hour. Tested and ready for action upon arrival. Made to fit farmers' needs. Other sizes up to 800 h. p. Write for free catalogue.



WEBER GAS & GASOLINE ENGINE COMPANY, Box 176, Kansas City, Mo.

Shepherd's Aerator

is most simple, most effective, least trouble. While you go on milking millions of air globules from the charged tank are passing up through the milk, driving out all animal heat and foreign odors. Works in shipping can. No other vessel to clean. **King among Aerators.** All dairymen prize it. Write for descriptive circular.

BINDER TWINE FARMERS wanted as agents. AUGUST POST, Moulton, Iowa.

as follows on the advantages of cultivating the field with disk cultivators:

By disking alfalfa, is meant the going over it in the spring, before growth starts, or in the summer, immediately after cutting, with a disk harrow. It is customary to set the disks at a slight angle. This cuts the crown roots and stirs the soil. Both our old alfalfa field and the one seeded last year were disked in August, this season, immediately after cutting the crop. The disking appeared to be beneficial to both fields as it was followed by a vigorous growth and a general branching of the crown roots. Seed was sown where the alfalfa was thin, which, while it sprouted, was soon shaded and choked out by the growth of the old plants, except where the ground was nearly bare.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—On the Elgin Board of Trade today, the price of butter was made firm at 21c. New York was reported steady at 22c., receipts 5,659 lbs.

Cheese—Choice, old, 14½c; new, 12¼@12½c: Wisconsin 12@12½c.

Eggs—Near by, 20c; Western selected, 16@16½c; fair to good, 15@15½c. Illinois, 16½c; western dirties, 12½@14c.

UTICA, N. Y., May 18—Cheese—Large, 1,800, 11¼c; small, 2,000 11½c. New York advices being firm; this market has stiffened.

CANTON, N. Y., May 18—Offered 210 boxes of large cheese; 1,392 Twins and 841 tubs of butter. at 21½c. 10¾ bid for large cheese; Twins at 11½.

NEW YORK, May 18—Butter—Receipts, 5,659; lbs.; firm; extra creamery, 22c; creamery, common to choice, 18@21½c; state dairy, 17@21c.

Eggs—Recipts, 15,900; state and Pennsylvania, 16½@17c; western storage, packed, 16½c; western firsts, 16¾c; Kentucky, best, 15@15½c; southern, best. 14½c.

Cheese—Receipts, 1,335 pkgs; steady; state full cream, fancy, small, colored and white, new, 12¾c; new large, colored, 11⅞c; new, large, white, 11¾c.

NEW YORK MARKET

NEW YORK, May 16th.—Butter—Receipts for the week, 36,746 packages. Exports for the week, 57 packages.

Market has been active and strong all the week, and closes with a scarcity of Extra Creamery, and prices exceeding our quotations for highest scoring butter. Good creameries were in demand at 21 to 21½c, and middling to poor ones sold at 18 to 20c.

New York state dairy, when strictly fancy, sold at 21 to 21½c, while odds and ends of all styles, quality and packages sold at 18 to 20c. All under grades Western are in light stocks and prices firm with advancing tendencies. Renovated neglected and prices nominal. We quote:

Creamery, extra, 21@22½c medium, 21@21½c; poor, 16@20c Dairy, extra, 21@21½c; medium, 18@20c; poor, 15@17c. Ladle, creamery, extra, 18@19c: medium, 16@17c; poor, 14@15c. Renovated, extra, 18c; medium, —poor, 12 to 15c.

Cheese—Receipts for the week, 26,744 boxes. Exports for the week, 14,733 boxes.

Arrivals of new cheese were quickly taken and prices slightly advanced over last week, and firm at the close. Old Cheese are being peddled out in the smallest kind of way at 13@14c.

Skimmed Cheese is more plentiful and sold freely for export at 4 to 6c. We quote:

Full cream, new extra, 12¼@12½c; medium, 11½@12c; poor, 8@11c.

Eggs—Receipts for the week, 112,931 cases.

Continued heavy receipts are having a depressing effect on prices; stocks are accumulating, and to make sales lower prices have to be accepted. We quote:

New York & Penn., fancy, per doz., 16½@17c; Northern & Western, fancy, per doz,, 16@16½c; All Sections, poor to good, per doz., 13@15c.

BALTIMORE MARKET.

BALTIMORE, May 14—Butter — While the receipts of creamery, since our last issue, have been gradually on the increase, and advices from the dairy sections report that the conditions are favorable for a much larger increase in the make in the near future, the steady feeling, noted in last issue, continues to prevail, and the recent advance in Elgin has had the tendency to strengthen the belief that the bottom on fancy stock has been reached. Although the order trade has been rather light, and absolutely no speculative buying worthy of mention, the local consumptive demand has been very good and all attractive offerings have met ready sale. Fancy makes of imitation creamery are in active demand. Fresh sweet ladles are in light supply and good request. Rolls—After this week we will discontinue quotations. Choice sweet packing stock is wanted. Blocks and prints continue in full supply; there is a vast difference in quality. The market generally rules firm on all desirable offerings.

Creamery Separator, extras, 22½@23c; firsts, 21@22c; seconds, 19@20c. NOTICE
TO SEPARATOR INFRINGERS.

Several concerns have of late been trespassing upon some of the DE LAVAL patents and a few months since suits were brought in the United States Courts against the American Creamery Supply Company of Waterloo, Iowa, and others. An injunction has now been issued, as follows, **of which all infringers are warned to take notice.**

THE PRESIDENT OF THE UNITED STATES
TO

AMERICAN CREAMERY SUPPLY COMPANY, its associates, officers, attorneys, solicitors, clerks, servants, agents, workmen, employes; GREETING:

WHEREAS, it has been represented to us in our Circuit Court of the United States for the Eighth Circuit and Northern District of Iowa, Eastern Division, that Letters Patent of the United States were issued to John Joseph Berrigan, assignor of the De Laval Separator Company, in due form of law, on the 2nd day of January, 1900, No. 640,358 for Improvements in Centrifugal Cream Separators, and that you, the said American Creamery Supply Company, have infringed the same;

NOW, THEREFORE, we strictly command and enjoin you, the said American Creamery Supply Company, and your associates, officers, attorneys, solicitors, clerks, agents, servants, workmen and employes, under the penalties that may fall on you in case of disobedience, that you forthwith and forever disist from, directly or indirectly, making or causing to be made, using or causing to be used, or vending to others to be used, in any manner, any centrifugal cream separators, devises, or apparatus containing, embodying or employing the said inventions and improvements granted by said Letters Patent, or from infringing upon or violating the said Letters Patent in any way whatsoever.

WITNESS THE HON. MELVILLE W. FULLER, Chief Justice of the United States, at the City of Dubuque, State of Iowa, on the 4th day of May, 1903.

(SEAL) A. J. VANDUZEE, Clerk U. S. Circuit Court, Northern District of Iowa.

MARSHAL'S RETURN:

This writ came into my hands for service on the 4th day of May, 1903, and I certify and return that I personally served the same upon the American Creamery Supply Co., by service upon Warren Cranston, President of said Company, by offering to read the same to him, the reading thereof he waived, and by delivering to him a duplicate original of said writ, at Waterloo, Blackhawk County, Iowa, on the 5th day of May, 1903

EDWARD KNOTT, U. S Marshal, By J. W. Philpot, Deputy.

UNITED STATES CIRCUIT COURT IN AND FOR THE NORTHERN DISTRICT OF IOWA:

I, A. J. VANDUZEE, Clerk of United States Circuit Court in and for the Northern District of Iowa, do hereby certify that the foregoing transcript contains a full, true and complete copy of the Injunction issued under seal of said Court dated May 4, 1903, in the case entitled "The De Laval Separator Company vs. American Creamery Supply Company, No. 230 Equity" together with the Marshal's return for Service endorsed thereof, as full, true and complete as the Original of said Injunction duly served, remains on file in my office in Dubuque, Iowa, under date of May 8, 1903

IN TESTIMONY WHEREOF, I hereunto subscribe my name and affix the seal of said

(SEAL) U. S. Circuit Court at my office in Dubuque, Iowa, this 8th day of May, 1903.

A. J. VANDUZEE, Clerk U. S. Circuit Court, Northern District of Iowa.

Wanted—Position by cheese maker in up-to-date factory. Dairy School experience. Also can give reference. Address L. L. H., care of Hoard's Dairyman. 14-2

Mr. Grote Takes Liberty to ask a few Questions. Some Pertinent, Others Less Important.

ED. HOARD'S DAIRYMAN:—I have frequently read the statement that the DAIRYMAN is issued for the purpose of answering questions. I take therefore the liberty to ask a few questions for you to answer whenever you do not know how to kill time.

1. What is the reason that almost all women are afraid of a mouse?
2. Is this fear based on prejudice?
3. What is prejudice?
4. Is it not a pre-judgment of a case on which you have no evidence, or not sufficient to make a judgment valid?
5. The common farmer pre-judges his cases on evidence furnished by tradition based on the experience of former generations.
6. Does the DAIRYMAN do the same thing?
7. Has the DAIRYMAN no prejudices based on customs and traditions and for which it has no valid proof?

In a former issue the DAIRYMAN says: "A cow of pronounced dairy temperament can not eat and digest enough roughage to furnish sufficient raw material from which to elaborate milk up to her capacity."

As this is a point of great interest for all dairymen will the DAIRYMAN kindly publish the proof for this broad assertion?

In last paper the Editor says: "We think that cows will do fairly well on clover silage and clover hay alone, but better and with more profit, if they have some grain in connection," page 258. As this assertion is also of importance to all dairymen will the DAIRYMAN kindly publish the experiments and figures by which this assertion is proved?

I do believe that both of these assertions are a pre-judgment on insufficient evidence. At least I have tried to find valid proof for them and so far I have failed.

It has been said that the more a man learns, the more he comes to the conclusion that he knows nothing. All human knowledge is relative. We find that when we do certain things under certain conditions, we obtain certain results, and we reason that if we repeat this action under the same conditions, we get the same results. Our knowledge is, therefore, relative to these experiments, and that is the only knowledge humanity has.

If the conditions are not exactly like the conditions in the first experiment, the results may be quite different. As the foregoing is the only method, is the only one by which certain facts can be established, it is of great importance for all dairymen to know how the above facts given by the editor of the DAIRYMAN have been so far established as to convince the editor that they are true, and full explanation will be therefore appreciated.

It must be self-evident to any man fully acquainted with the condition in which the majority of our farmers live, that the purchasing of feed and the exchange of feed raised on the farm for by-products of our factories, is in most cases impracticable and unprofitable. A farmer or dairyman should always figure to make his business independent of every other business. He should farm his farm in such a manner as to raise all the feed necessary to keep all his stock of whatever kind, profitably. It does not pay him to raise grain to exchange for other grain and get nothing for handling and hauling the grain. He should keep the necessary number of the right kind of stock to eat up all the grain he raises. The assertions that he can profit by exchange of grain for feeding purposes are illusions. When he sows the grain, he should sow the kind he needs and keep the kind of stock fit to eat this grain at a profit, etc.

Please send me address of your correspondent who used a sweep power successfully for milk skimming.

Mauston, Wis. C. W. GROTE.

Our correspondent's first inquiry does not appear to be particularly important except by way of illustration and comparison, and in this respect, it falls under the fatal objection that comparisons between things which differ materially are often, if not always, misleading. Moreover, it may be questioned whether "Almost all women are afraid of a mouse," *per se*. Women's attire offers such a convenient refuge for a frightened mouse that it is no wonder she seeks a chair or some other elevation until the little animal has found safety elsewhere. This is not prejudice on the part of the woman, as we understand the meaning of that term, but a very sensible conclusion from premises that cannot be successfully controverted.

Our correspondent unconsciously betrays an early education in the so-called classics, especially in Latin, from which so many of our words are derived, and not unlike a good many other classical scholars, he permits etymology to outweigh common every-day experience. Prejudice is literally pre-judgment, but by use and *metastasis*, the word has lost its literal significance largely, and now in common speech, it is used mostly to represent a state of mind and judgment which refuses to accept the evidence which to others may be conclusive. Emerson well says, "Difference from me is the measure of absurdity," and it is not at all uncommon for two men to be in possession of the same facts and yet come to widely differing conclusions, each thinking that the other is the victim of prejudice, but not necessarily due to pre-judgment. Why is it that juries so often fail to agree, or why is it that political parties divide so sharply on such questions as tariff? Is it because of prejudice or pre-judgment? It may be sometimes, but certainly not in the great majority of cases.

Or, to draw illustration at closer range, why is it that our correspondent claims that "it must be self-evident that the purchasing of feed and the exchange of feed raised on the farm for by-products of our factories is, in most cases, impracticable and unprofitable." It would seem that the simple fact that thousands upon thousands of successful dairymen do purchase feed and do exchange feed raised on the farm for by-products, would suggest to Mr. Grote that his statement in this behalf indicates a condition of mind not far removed from prejudice. Likewise, his calling upon us to submit proof or evidence of the correctness of the two propositions he quotes, seems to us to savor more of the dialectician than the experienced cow-keeper. We will, however, endeavor to submit a few facts in corroboration of these statements for our correspondent's further consideration.

Experience has demonstaated over and over again that the average good cow cannot dispose of more than about twenty-five pounds of dry matter in her feed

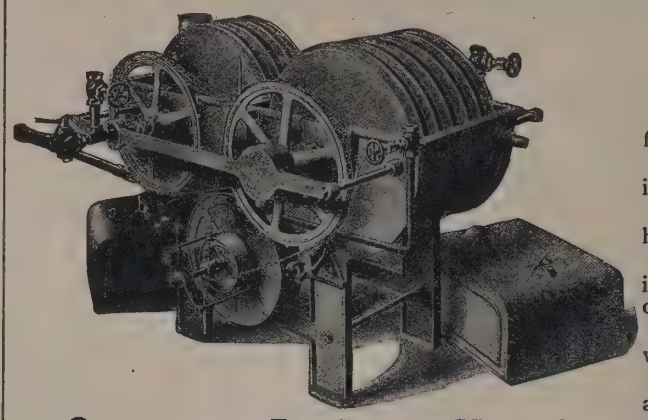
"ADVERTISEMENT."

BE INDEPENDENT.

It's Easy to Shake Off the Coffee Habit.

There are many people who make the humiliating acknowledgment that they are dependent upon Coffee to "brace them up" every little while. These have never learned the truth about Postum Cereal Coffee which makes leaving off coffee a simple matter and brings health and strength in place of coffee ills. A lady of Davenport, Iowa, who has used Postum Food Coffee for five years is competent to talk upon the subject. She says:

"I am a school teacher and during extra work when I thought I needed to be braced up I used to indulge in rich, strong coffee of which I was very fond and upon which I thought I was dependent.



"I began to have serious heart palpitation and at times had sharp pains around the heart and more or less stomach trouble. I read about Postum and got some to try. I dropped coffee, took up the Postum and it worked such wonders for me that many of my friends took it up.

"In a short time I was well again, even able to attend evening socials. And I did not miss my coffee at all. Now I can truthfully say that I have been repaid fully for the change I made. I have no indications of heart disease and not once in the past four years have I had a sick headache or bilious spell.

"My father, 78 years old is a Postum enthusiast and feels that his good health in a large measure is due to the 6 cups of good Postum which he enjoys each day." Name furnished by Postum Co., Battle Creek, Mich.

There is a reason.

A CHANCE TO MAKE MONEY

I have berries, grapes and peaches a year old, fresh as when picked. I used the California Cold Process. Do not heat or seal the fruit, just put it up cold, keeps perfectly fresh, and costs almost nothing; can put up a bushel in 10 minutes. Last year I sold directions to over 120 families in one week; anyone will pay a dollar for directions when they see the beautiful samples of fruit. As there are many people poor like myself, I consider it my duty to give my experience to such and feel confident anyone can make one or two hundred dollars round home in a few days. I will mail sample of fruit and full directions to any of your readers for nineteen (19) 2-cent stamps, which is only the actual cost of the samples, postage, etc. FRANCIS CASEY, St. Louis, Mo.

HOARD'S DAIRYMAN

The BEST Dairy Educator in the world.

during the twenty-four hours. Thirty pounds of timothy hay contains 25.69 pounds of dry matter, in which there is .84 pounds of digestible protein, 13.02 pounds of carbohydrates and .42 pounds of ether extract or fat. These amounts of digestible nutrients are more than enough to maintain the cow, but there is not enough protein to enable the cow to make very much milk after supplying the needs of her body. The statement of this fact, as it seems to us, is sufficient to justify the conclusion that a cow of pronounced dairy temperament cannot eat and digest enough roughage to furnish sufficient raw material from which to elaborate milk up to her capacity.

The second proposition for which our friend demands the proof, is that the cows will do fairly well on clover hay and clover silage alone, but better, and with more profit, if they have some grain in connection. Remembering that the cow's capacity for feed is as a rule, not much above 25 pounds of dry matter, we will suppose that she is fed thirty pounds of clover silage and twenty pounds of clover hay. These, if of average quality, will contain 25.34 pounds of dry matter, 1.96 pounds of digestible protein. 12.21 pounds of digestible carbohydrates and .64 pounds of digestible ether extract or fat. The digestible nutrients in a ration of this character would be quite sufficient to enable a cow to do quite well, were it not for the circumstance that a goodly proportion of the nutriment in such a ration is required to enable the cow to digest so much coarse fodder.

Every vital function is carried forward at the expense of energy, and nutriment is the only source of vital energy. In timothy hay only 45 per cent of the protein is digestible. In clover hay 55 per cent is digestible; in bran and oats about 79 per cent is digestible; in gluten feed, 86 per cent; in linseed oil meal, 89 per cent. It is plain, therefore, that it requires the expenditure of more energy to extract a pound of digestible protein from timothy hay or clover hay than it does from bran, or oats, or gluten feed, or oil meal. Hence, although our ration of clover silage and clover hay shows 1.96 pounds of digestible protein, no inconsiderable part of this protein has been used up in separating the digestible part from the indigestible part, and there remains, therefore, so much less that can be used as raw material for the manufacture of milk.

We presume that our friend will not contend that wheat straw, for example, is a good feed for milch cows as clover hay, and he will not demur to the assertion that the reason for this is that clover hay contains more digestible nutriment than does wheat straw and does not tax the capacity and energy of the cow to the same extent. For precisely similar reasons, it is advisable not to limit a cow exclusively to so good feed as clover silage and clover hay alone when grain can be had at reasonable prices.

The illustration on page 276 will probably prove a sufficient answer to proposition 8 in our correspondent's communication.

A New Cure For Milk Fever.

M. Emile Thierry has contributed to the *Journal d'Agriculture Pratique* an account of the new treatment of milk fever (parturient apoplexy) discovered and practiced with success by M. Knusel, a veterinary sugeon at Lucerne. The treatmemt consists of the injection of pure oxygen into the udder. M. Knusel had previously practiced the comparatively new treatment with iodide of potassium, administered sometimes through the mouth and at other times by injection into the udder; but he had found it to fail in the most serious cases, and he reckons that about 40 per cent of the cows treated with it were lost.

This insufficient success led him to try the oxygen treatment, which he had applied in twenty-two cases, when he wrote his memoir of the method. Some of the cows were in an extremely dangerous condition, prostrated, insensible, and with labored respiration, accelerated pulse and paralized tongue. Yet in thirty to sixty minutes after the injection they had so far recovered as to seek for food. Not one of them died. From six to ten litres of oxygen were injected, the gas being compressed to twenty-five atmospheres in an apparatus obtained from a firm of Hauptner of Berlin, which contains a valve for regulating the pressure.

After washing and disinfecting a teat he introduced the teat probe, and slowly opened the tap to release the oxygen. When two quarters had been filled an assistant compressed the two teats, and by massage the gas was distributed through the glandular tissues. This operation having been completed, it was repeated with the other two quarters, the whole work occuping only about ten minutes. Gradually the treated cow showed signs of recovery, first raising her head, next shifting into a comfortable position, and soon getting onto her feet.

In two instances a relapse occured. through the cows having been milked too soon; but a fresh insufflation if oxygen quickly restored them. These were the only accidents in the twenty-two cases. M. Knusel believes that of his treatment be applied soon enough, it will be successful in all cases. He suggests, as the explanation of the effectiveness of oxygen, that the poison formed in the udder and passed into the general circulation of the animal is produced by micro organisms, which may be anaerobic, and therefore unable to live in the presence of oxygen.

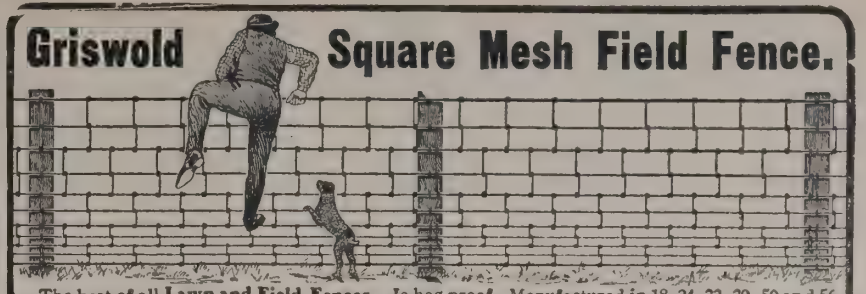
Seeing your friends and having them join in for a good club of subscribers.

To Bring up a Run-Down Farm.

ED. HOARD'S DAIRYMAN:—Two years ago we got in possession of a 100 acre farm here which has been run pretty hard for a number of years, and has almost no grass on it. Our seeding the first year failed, the weather was too dry in fall and spring. Last year we tried cow peas, but did no good. Recently we got one of John A. Salzer's Seed Co., La Crosse, Wis, catalogue. In it they have many wonderful things. One of them is the "Billion Dollar grass." They claim it would grow up in six weeks ready to cut a big crop. Do you know anything about it, either seen it or heard of it? Please let me know, either through the paper or privately, or what would you advise sowing for hay, to be fed to milk cows and horses in conjunction with corn fodder for roughage?



We have just finished sowing a six-acre field in alfalfa, but cannot expect much hay from it this summer. Any information on these questions would be thankfully received. J. J. S.

Bedford, Pa.

It is a very hazardous undertaking indeed to advise, at such a long range, just what to do to bring up a run-down farm, or what sort of a crop to sow to furnish hay for the coming winter. We have no personal knowledge concerning the Billion Dollar grass advertised by the Salzer Seed Company. We do know, however, that it is a reputable firm, that the statements in its advertisements and catalogues are fairly reliable, but we cannot advise any one to rush headlong into experiments with new varieties of seeds. A grass that may be well adapted for some localities, might prove practically worthless in other localities. Take the question of alfalfa for an example. The editors of HOARD'S DAIRYMAN have had very gratifying success with it, but they commenced in a moderate way at first, and have learned by practical experience some of the conditions which are indispensable to success with this plant, and their advice to others, notwithstanding their personal success with alfalfa, is to commence in a moderate way.

If nothing better offers, our inquirer can raise a crop of fodder corn by planting some very thick in drills on well-prepared ground about the last of June, cutting and curing it as for hay. It is too late now perhaps, but in ordinary seasons, oats and Canada peas sowed at the rate of a bushel and one-half each to the acre, usually make a very fine crop of hay. Possibly, common millet or Hungarian grass offers a very satisfactory solution of the present problem, and when the present year's crops are removed, nothing perhaps will tend to bring up this run-down land better than to sow crimson clover early this fall for plowing under next spring.

Griswold Square Mesh Field Fence.

The best of all **Lawn and Field Fences.** Is hog proof. Manufactured in 18, 24, 33, 39, 50 and 56 inch heights; in 20 and 40 rod rolls. Note and Comment.

Roads.—Concrete Silos.—Land in Dunn Co., Wis.—Cement Floors for Cow Stables.—Farm Lands in Northern Ohio.

ED. HOARD'S DAIRYMAN:—In the April 24th number of HOARD'S DAIRYMAN, there is an illustration in regard to good roads, wherein one man is shown trotting his team with heavy wagon attached, loaded with 4,000 lbs. of wheat, and another teamster, not four rods away, stuck in the mud, his team not being able to draw an empty wagon. The remedy is shown, but not made either the text, or sermon. The road fence, is a four foot high, stone wall! Why is not this wall put into the road, and pounded down smooth and thus enable the one man to draw the same load easily with one horse; and the second man get home in time for supper.

While in Central New York, we were guests of Hon. F. E. Dawley, the Supt. of Institutes, and a horrible road, for 175 years near his home, had been made into a fine boulevard by putting the stone walls from either side of the road into the path, and rolling and crushing them down smooth with a steam roller, and had settled one question, what to make roads of,and how,in a stone wall country. True it did not take the "steep" out of the big hill up to his house; but it did enable him and his neighbors, to haul big loads down the hill, at any season of the year, and not have their farms sold by the county for the building of the miles of fine road in that section.

The real road problem to be solved, is in localities where there is nothing but more mud to build a road of, and every farmer kicking about the cost. We know of one man who kicked about the cost, when told that the streets of heaven were paved with gold, and said "that that seemed an awful foolish and unnecessary expense. If they had worked out their taxes on the road as they should, they could have saved bonding the town."

* * * *

There seems to be a revival of the idea, or plan of concrete silos, in some sections, though for a time they were wholly discarded. The great weakness in them to be overcome is cracking and springing by the pressure of the silage, and to remedy this, some have hooped them and some build them inside of a tub—a wooden hooped silo. Lately we came across one that while it had iron-rod hoops, they were built into the interior of the walls as the concrete was added. Half inch steel rod hoops were put into the wall, each 18 inches, and bedded in the cement. This would add great strength to the structure, and it would not be necessary to make the walls to exceed 15 inches in thickness. We cannot see why good elm hoops, about 3×3 inches, made of about five layers of wood, would not be quite as well and quite as strong, and the cost of them would not be a fourth as much as the 18, or more iron rod stay hoops.

In the last DAIRYMAN is a notice of Dunn Co. Wis. farms for sale, which is a great surprise to me, that any one should want to sell out and leave a locality where soil is of the best, no crop failures, no drouths, sand, or pine stumps, near the best market, best dairy section on earth, all prosperous, and water every where! This seems to me to be an ideal place. This accounts no doubt for the great success of our old friend Theo. Louis, one of the greatest institute lecturers the west has produced. It does seem to us that we have seen some sand, and that drifting, in that Dunn Co., locality. We remember seeing a farmer there after a big wind digging out a board fence that had been submerged by the drifting sand to find the farm lines and it is reported that this same Theodore Louis, had an old fashioned stoned up well, some twenty feet in depth, and after a big wind storm, discovered that the sand had all been blown away from about the well nearly to the water. With the quick perception for which this man is noted, he propped up the walls to prevent their toppling over, and waited for another storm, which blew the sand back, and he now has the original well in good condition and daily use. That Dnnn Co. is only a short distance from the "Elysian fields" was generally understood, but that it was quite so near, is an unexpected bit of information.

I notice that HOARD'S is officially a little "fornist" the cement bed room floor for cows, and would prefer plank whereon this cow stands. I wonder if it is not somewhat in the construction of the cement platform that causes this dissent. The writer of this was recently in a $10,000 barn wherein a dairy was "Waldorf-Astoria-ed", and the cement floor was faultless except in this. The surface was troweled off with a steel facer, and it was as smooth as glass, and we saw two of the $300 cows slip and go down as they were being tied. The bedding was on the move toward the gutter all the time, from this very cause. Had the mason, when he put on the finishing coat, smoothed it down with a stub broom and left it rough, all objection would have been removed, as on this rough surface, the cow would have a good foot hold, and slipping would be out of the question, and on such a platform the bedding stays where it will do the most good.

It is almost impossible to so bed plank in cement,but that the liquids will not get under them, and then trouble commences with the sanitation, while with the other plan, and plenty of bedding, we cannot see any valid objection to a cement platform, either on account of supposed coldness, or liability of the cows bruising or injuring their legs in such a way as to produce stiffness of joints, or unnatural swellings. One who has ever taken up the planks of a stable floor, which has been in use to the point of wearing out, will have a recollection of a somewhat pungent odor, which will in no wise remind him of the "odors wafted from Araby the blest". With the present price of lumber, I am convinced the first lay of the cement is the cheapest, and if well constructed, will last until somewhere near 1950.

Something like 18 months ago, I wrote an item for HOARD'S about the cheapness of farm lands in northern Ohio, as compared with prices in other parts of the state. It showed what a good dual-purpose paper the DAIRYMAN is, for it brought me scores of letters from all parts of the United States east of Omaha, showing that the paper is both a good dairy, and advertising, medium. What was true then, is a fact no longer. The building of over 600 miles of trolley roads and 300 more building,on the "Reserve," mostly through sections remote from the steam roads, the building of rural telephone lines to the extent that 50 per cent of the farmers now have phones, rural delivery about complete, and 30 townships already with centralized schools, has had its great influence, and lands have gone up with a bound, and while prices are not so high, as in some other sections of the state, they are no longer given away, and a chromo thrown in.

There has been a great movement of the city men in country farm buying, and along the trolleys one now sees hundreds of these country seats, with their improvements costing from the tens to a hundred thousand dollars each, and all these combined, with what is known as the commuter influence, i. e., the great army who work, and professionals in the city, days, and live out from ten to thirty miles from the city along side the steam and trolley roads, has boomed the rural northern Ohio, as never before, and cheap lands are now scarce even at sheriff and administrator sales. I have closed my real estate office, and shall engage in other business for the present.

Ohio. JOHN GOULD.

The Great Value of a Good Milker.

L. O. Jackson a southern dairyman, writes the *Jersey Bulletin* and gives the following from his own experience to show how much more a good milker is worth than even an ordinary one. He says:

Over and above all else, we want educated men to handle these cattle from calfhood to maturity,whose reliabillity will insure the proper raising and development of their capability. One might say that he could not afford to pay the salary that an educated herdsman would command. You can't afford not to do it, if you would make a success of the business.We that dairy for a living with hired help,must have better help or quit.

To illustrate, for I want to tell you about a good milker, and then a better one: Last year I had a $25-per-month milker, getting from 16 cows 23 gallons per day. I thought he was doing pretty well—above the average. But he had to take a rest, so I employed an intelligent milker on the 13th of February, and from the 17th of February to the 17th of March, the cows went up to 32 gallons per day, with the same surroundings, quantity and quality of feed, and they sustained the increase, doing

N. H. ROBINSON, Prop., Centralia, Wis.

FOR SALE.
JERSEY BULL, one year old. Good individual of the best breeding. Also 7 months bull from tested dam. Herd headed by Fontaine's Owl, 60436. Prices on application. Address,
J. F. EGERTON, Footville, Rock Co. Wis.

The Evergreen Farm Herd has for sale three or four A. J. C. C. heifers bred Also a few cows and some choice bull calves from two to six months old. Write for pedigrees and prices.
N. N. PALMER & SON, Brodhead, Wis

even better. This gain of nine gallons stood for $2.25 per day, as I sell pure Jersey milk for 25 cents per gallon the year round. I consider that if the first man was worth $25 per month, the second was easily worth $65, although he did not cost me near so much.

Let's get rid of the poor dairyman by substituting a scale of points for better ones, basing his salary upon his efficiency To say: Skillful reliability in—

	Points
Feeding dairy herds	20
Milking	20
Calf raising	20
Cleanliness in all things	10
Patient kindness	10
Doctoring	10
Emergencies	10
Thus we have	100

HOARD'S DAIRYMAN would suggest several points that would help educate good milkers very much. 1. Let every dairy farmer exercise kindly patience and good treatment towards his cows. Suppress all boisterousness in the stable. Give the men plenty of time to do the milking. It is the most important work of the day.

2. Take pains to teach hired men what constitutes good milking. Do the teaching in a kindly way, not in a fault-finding manner.

3. Let every hired man act as though he was willing to be taught and shown.

Use of Lime in Butter Factories.

The Danish Dairy Instructor, B. Boggeld, in a recent lecture, dwelt at length on the use of lime in butter factories.

He said that there is often occasion to emphasize that it may be necessary to distinguish between cleaning and distinfecting. It must be conceded that the cleanliness with which we—for practical reasons—must be satisfied with in our factories, in no way satisfies the strict demand of the hygienism which must be applied in fighting contagious diseases in a herd; but on the other side it is generally acknowledged that the best possible cleanliness is equally desirable on account of the health of the cows and the development of their disease resisting powers, as it is of great importance in securing of fine and uniform dairy products.

Ten or twenty years ago heat was used in the fight against bacteria. Steam was employed liberally, and the result was the warping of churns and cream barrels. The floors were scrubbed with boiling water, and it was even proposed to scald the drains, which increased instead of decreasing the smell. At present it is an exception when a churn is steamed. All wooden utensils are rinsed and scrubbed, first with cold or luke-warm water to remove the milk, and then they are covered with a coat or thick mush of slacked lime. After ten or twenty minutes or later, the churns (or other utensils) are scrubbed with the lime and cold water, after which they are rinsed twice in warm water and at last with water hot enough to make the wood dry quickly.

Lime is used for cleaning in nearly all Danish factories, not only for woodenware, but also for tinware, and for scrubbing the floors. It took some time to introduce it, as the butter makers, to begin with, had their hands affected by the lime, but when they once learned to use it, they had no trouble, and the use of steam as well as of soda has been reduced. Lime is now also used more and more in place of oil-paint, which is often ruined by the dampness or heat in the factories, and as porcelain tiles are, as a rule, expensive, whereas lime is cheap and easily applied. It is often objected that the lime will peel off, but the lecturer did not deem that a drawback in the factories or cowsheds, because it was so much easier to clean. To wash a painted wall is no easier than to brush off a white washed one with a stiff brush and give it a new coat, and it is certainly cheaper to start with.

Some Comments from New Hampshire.

ED. HOARD'S DAIRYMAN:—I will try to get a few subscribers for the DAIRYMAN. Will you please send me a few sample copies, and I will leave them with my neighbors, and tell them "what is what."

I planted a plot of alfalfa in 1901, but not understanding the plant's needs, I let the weeds grow. There are today plants growing (in witch grass), that are ten inches high and as large around as a two-quart measure. I shall try a lot next spring.

M. C. S., Brocton, Mass., I have only farmed for about five years, but I will say that the cows that I started in with were discarded for those that I raised, with one exception.

Save the calves from your best cows and the best bull that you can secure, saving those calves that have a good milk mirror or escutcheon and well placed teats. Your cows having been bred will give more milk for two or three months at least.

Bulletin 58 New Hampshire Agricultural Experiment Station gives the cost of raising calves up to 16 months, as about $28.00, and she should weigh from 600 to 700 pounds.

Massachusetts Experiment Station report for 1893 gives the cost of raising calves up to 12 weeks as $5.07, average cost of whole milk, skim milk and grain. H. A. T.

Concord, N. H.

Special prices on young bulls from A R. O. cows. Also Yorkshire pigs of most approved breeding now fit to ship.

Calf Raising.

This question, important as it is to every farmer, is very lightly thought of and valued. A large proportion of farmers will stuff a hog to the verge of cholera and treat a calf as though it was a nuisance and burden. A look at the calves on a vast number of farms run by men who think they are dairymen, is sufficient to prove that they really do not know the first principles of calf raising. Our contemporary, the New York *Produce Review*, has presented the following summary of thought and quoted authority on this question. It is worth reading and studying:

This is one of the greatest problems which confronts the patrons of the separator creamery and yet more those of the cheese factory.

In some districts—Elgin, as for instance—many of the farmers solve the problem by not raising any and buy general-purpose cows from Iowa, selling them for beef when dry.

While this system may sometimes pay the individual, it has the great drawback that it destroys the good heifer calves which should have been raised and thus is a detriment to the industry as a whole. *To kill the heifer calf, from a good cow, is a crime.*

And, as a rule, it does not pay. The individual who sells his skim milk for a song (10 to 15c per 100 lbs.) for casein throws away not only the best market for it—the calf—but loses the manurial value and devastates his farm.

W. D. Hoard never propounded a better text and never preached a better dairy sermon than those preached on that text. It is indeed the keynote to successful calf raising. Remember the calf is a baby.

On this question opinions differ greatly and while our experience is in favor of never letting the calf suck, Prof. Haecker lets them suck once, and Major Alvord says:

"The separation may be delayed until the dam's milk assumes the normal condition, but, as a rule, the earlier the calf is taken in hand and its feedings regulated the better for the calf."

It depends somewhat on the disposition of the cow; if she is very nervous, it may be best to let the calf suck once or twice—always milking the cow dry afterward—but we found it sufficient to tie up the calf in front of the stanchion where the mother could lick it while the milking was done, and after a few times the cow seemed to "adopt" the milker.

The general impression is that skim milk from separator creameries is not worth as much within 25 per cent as that from a hand separator. We shall not deny that in some cases it may be so. If the creamery accepts dirty and half sour milk from the farmers and then runs the skim milk into a tank (underground or above ground) which is never emptied, never cleaned or only cleaned two or three times a year, then we may be inclined to accept the claim.

But if the creamery operator accepts only good milk, if he heats the skim milk to 180° or more, if he runs it into a tank which is emptied and cleaned every day as carefully as the receiving tank, and if this hot milk is run into the milk cans so as to heat the little rest of new milk in them to at least 160°, then that milk, when arriving at the farm, will have a feeding value equal (or at least within two or three per cent) to the hand separator skim milk. And it will have the further advantage that if one or two cows in a herd should suffer from tuberculosis, there will be no danger of transmitting it through the milk.

Some prominent dairy experts practice and advocate feeding only twice a day. Thus Prof. T. L. Haecker in describing how he fed the calf Omaha's Potty says:

"She had her mother's milk one week—sucked once—then in 24 hours received 4 lbs. fed twice a day, making 8 lbs. per day. The 2d week 4½ lbs. new milk and 4½ lbs. skim milk (sep); 3d week 7o lbs. skim milk and ¼ lb. flax meal; 4th and 5th weeks 77 lbs. skim milk and ¼ lb. flax meal, hay, 3 lbs.; 6th to 10th weeks 91 lbs. skim milk and ¼ lb. flax meal, hay 5 lbs., and balance of time during 6 months, 13 lbs. skim milk, and prairie hay."

In spite of this, we believe, from watching the calves who run with their mothers, that it is a better plan to feed three or even four times a day for the first two or three weeks. Nor are we alone in this opinion. Thus Major H. E. Alvord says "feed three times, preferably four" and W. D. Hoard says:

"Nature when left to herself' turns the baby calf out with his mother and he will take his food from ten to twenty times a day. If you will follow that law and give the calf his food as often as possible, give it in small quantities and give it as the mother gives it, sweet and warm, you will come as close to nature as you can."

While we prefer not to let the calf suck we deem it important the first two three days to give each calf not only colostrum but that of its own mother. We believe nature provided in each case the proper composition of the milk for the calf, and hence it should be safest to use it instead of taking the milk indiscriminately from any fresh cow. To give a new born calf milk from a cow that has been milked six or seven months is at least to tempt Providence.

While we believe some dairymen go too far in the direction of half starving the calves, there is no doubt that many more give too much. No rules can be laid down and the quantity should be in proportion to the size of the calf. In feeding Omaha's Potty, Prof. Haecker gave only 8 lbs. per day the first week, but this is surely the lowest limit, and if fed three times a day 10 or even 12 pounds may not be too much. Often the ill effect of *quality* (dirty and too cold) is blamed on the *quantity* given.

While we prefer to give a calf new milk for 2 weeks, it may be enough to give it for one and then commence gradually to put in more and more skim milk so that it gets all skim milk at the beginning of the third week.

THE MILK SHOULD BE WARM.

Of utmost importance is the temperature of the milk when given, and it should be within a few degrees of blood-heat—98°—in cold weather say 100 to 104 and in warm weather 90 to 94. Of course, as the calf grows older, this is not so important though we should always beware of having it too cold—or too hot.

Regular feeding hours are essential and the custom of feeding the calves—or any other animal—at any old time when other work is done, should be abolished. All kinds of work are much easier when it is done at regular hours, and the effect of regular meals on calves as on men is certainly beneficial.

Having deprived the milk of its fat, we must restore it and for this purpose a small amount of flaxseed jelly, oilmeal, oatmeal or oilmeal and corn meal as recommended by various authorities; but flaxseed jelly containing all the oil in the seed seems to us the best substitute for the butter fat—and we want to add that the more this is emulsified with the milk, the better it is.

Prof. Henry recommends adding a tablespoonful of oilmeal boiled to a jelly, and Prof. Haecker gave the before mentioned calf 70 lbs. of skim milk and ¼ lb. flax meal during the third week. It seems to us, however, that we may safely go further and give at the rate of 2 lbs. of meal and more to 100 lbs. of skim milk,, but the all important part is to watch the excrements and feed accordingly.

Prof. Henry in his valuable work on feeds and feeding recommends to give a pinch of whole oats after the milk when two weeks old, and while the calf may first spit them out he will soon learn to chew them. At first a couple of tablespoons but when 12 weeks old and getting 20 lbs of skim milk daily, he will eat one to two pounds.

A pinch of hay should be given, first to amuse the calf, and later as part of the feed.

While thus no hard and fast rules can be laid down, the feeding must be regulated according to the purpose. If a heifer calf, it should be kept in good growing condition, without getting fat, but if baby beef or a steer is to be developed, it is well to keep it fat all the time. For this reason oatmeal may be preferable for the former and corn meal for the latter purpose.

Major H. E. Alvord says: "When pasturage is good after the calf is six months old, there can be no better food. At other times let the food be mainly the coarser and more bulky kind of forage; the digestive appetite needs to be developed and become accustomed to working up large quantities of food. A big belly may result but no matter."

Hay tea, which is best from early cut hay, is improved by boiling it down so as to concentrate it somewhat. Prof. Stewart had success in feeding two gallons with ¼ lb. flaxseed and ¼ lb. wheat middlings boiled in it, to calves 36 days old, increasing the middlings to 1 lb. per day.

Mr. H. E. Cook says, anent feeding whey, which he considers worth from 7 to 10c per 100 lbs. "Whey should be kept sweet and clean. Start with new milk for one or two weeks, then change

THE ECLIPSE Cream Separator

PRICE $30 UP.

Write for Booklet.

We want to send you an *Eclipse Cream Separator* to try. It is built double strength all through and will last and work perfectly for a life-time. It acts twice on the milk and skims it absolutely clean. Its interior device is simple, easy to wash and to operate. Its double process removes filth from the milk as well as separating the cream, and leaves both pure and sweet and fresh. It never gets out of order. It is guaranteed.

It's a money maker and a money saver. It operates by hand, foot or motor power.

S. C. SULLIVAN, 425 W. 4th., Erie, Pa.

gradually to skim milk for two weeks and then gradually to whey, having meanwhile taught the calf to take dry, coarse food. Ground oats are good immediately after the milk or whey." Personally we have had no experience with feeding whey to calves, but it seems to us that it would be well to make a gruel of the whey and oatmeal, corn meal or flax meal.

This is sometimes a test of a good philosopher. A good way is to get astride the calf and backing it up against a fence having the milk in rather a shallow pail or basin, holding it up high, then wetting two fingers of one hand and putting them in the calf's mouth, taking care not to let the milk get into its nostrils. When the calf once has learned to drink, a bucket may be placed on the ground.

When several calves are to be fed and they have learned the trick, stanchions are a great help.

We shall only state that nine out of ten cases of disease are due to (1) dirty pails, (2) feeding too cold and too much, (3) changing from sweet to sour milk or *vice versa*, and (4) neglecting to keep the calf clean, dry and warm.

When feeding separator skim milk a few drops of rennet extract is a good preventive, and lime water is a good cure, for scours.

HOARD'S DAIRYMAN desires to add a word more to the above. It is upon taking the calf away from the mother. It is our belief and practice, that it is best to leave the calf with the mother, letting it suck in a natural way, for four days, in order to allay nervous excitement and reduce the chances of milk fever. If, in addition, the udder is not fully emptied during this time it will prove an additional preventive. After four days the danger of milk fever has passed, in most cases.

Cedar Hill Jersey Farm Notes.

Milk Fever—Milking Suits—Sowing Rape.

ED. HOARD'S DAIRYMAN:—My recent article on methods of milking at Cedar Hill College has brought several letters of both commendation and otherwise. One otherwise takes my system to task, because he uses white suits and covered pails and sells his milk beyond the price usually obtained by milk producers. That is all right if he can get a profit on the white suits and other extra work necessary to create an interest among milk consumers, who will pay an enhanced price for milk produced under such conditions, well and good. His milk is as good as we produce but no better. Some years ago the pasteurizing of milk was the fad.

Many dairymen spent large sums for outfits, and to-day most of these plants are idle. In our own case our faculty pasteurized one season, and our outfit cost us $3.00 and did the work just as well as the machines that cost several hundred. I only speak of this to show that practical results can be obtained with not much outlay of money.

The DAIRYMAN readers no doubt recollect of my asking, some years ago, for a receipt for milk fever so my boys could see a case. Three years ago, while attending our State Jersey Cattle Club banquet at Springfield, I made the statement that I never owned a cow that had the milk fever. The members of the Club told me that I would not be able to say the same thing at the next annual meeting. We have had two annuals since that time and not a cow has had the disease, and we have from 35 to 45 freshen every year. One Jersey breeder referred to me as a would-be dairyman who never had a cow good enough to have the fever. Well, if having the disease is a symptom of a good cow, we have a mighty poor herd, but my boys and girls still persist in having two pails when they milk some of our cows, and they are three-gallon pails at that. Twenty and twenty-three lbs. of milk at a milking should bring on an attack, I should think, and we have got 'em.

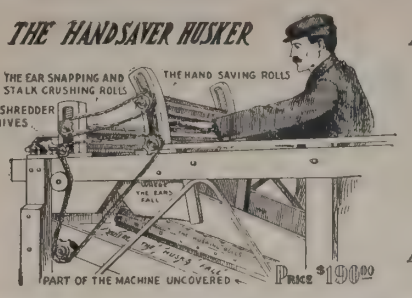
I am amused at some of the advertisements used by Jersey breeders in one of the leading journals that comes to my desk. One of them reads, "out of 25 cows, 5 of them have had milk fever." Another commenting on his bull, states that 50 per cent of his daughters die with the milk fever. Now who wants to buy either such cows or a bull with such a record among his daughters. I am sure I do not. I do not believe there is any more use for a herd of cows having milk fever than there is of their having seven year itch, lice or any other disease. Last week the *Jersey Bulletin* had a picture of a cow that had been cured of the fever, so it was stated. Our Professor of Dairy Husbandry made the remark that she looked as if she had just recovered from a severe attack of starvation.

One letter of inquiry asks me, "if you do not wear white suits, what do your milkers wear, blue bib overalls and white and checkered jumpers?—Um, Um,—the most of us do. I find that while we use the covered pail, white suits or other methods, a great amount of good or bad can be traced direct to those who have the cows and the barns in charge." In my own case, no one outside of my family has either the care of the cows, their milking or care of product. Three of my daughters assist in drawing the milk, follow it to the creamery and do not leave it till it is delivered by them either at express office or at door of consumer. These girls have been reared to know that perfect cleanliness, both in stables and creamery, is the only way to produce fine goods and the boys have been just as apt in the lessons.

Today, May 4, finds us yet with two weeks feed of silage on hand and cows on pasture, nights. We trust we may turn them on the day pasture without very much of a shrinkage. Last year our cows dropped over 100 pounds in milk yield when tapered off from silage to grass. In as careful a manner as we could, we weaned them to blue grass of as fine growth as we ever turned on, but the result was a shrinkage of one-sixth of their yield.

The faculty have just finished sowing 25 acres of rape for pasturing out young Jerseys and some 90 to 100 Berkshire pigs. With this acreage, we have the same feeling a man does who shoves back from an exceptionally good dinner, or finds he has a good balance in the bank, or has, after a long summer's work, finished filling his barns and silos. We feel we have an abundance of feed for everything, drouths or what not. There are no supplementary pastures I have ever seen that can compare to this.

Monmouth, Ill. BUFF JERSEY.



Butter for the Navy.

Messrs. Schulz, Niggle & Co., of San Francisco, who own and manage a line of creameries in California, advise us that they have been awarded the contract to furnish one-hundred thousand pounds of butter from pasteurized cream, to be delivered at the Mare Island Navy Yard in California. They expect to put up the entire quantity at their Diamond Crystal Creamery, located at Arcata, in Humboldt county, at the rate of about two tons a day.

COMMON SENSE Calf Feeder

awarded Gold Medal at Pan-American Exposition. The only Feeder adopted by experiment stations. It is the kind others try to imitate. Easiest to operate and clean.

Most Durable, Simple, Economical, Scientific and Practical.

Do not be deceived by imitators. Shams are never imitated. More Common Sense Feeders are in use than all others combined. Over 50,000 in use. No valves to get clogged or foul. Nipples reinforced and cannot collapse. The calf feeder is a perfect weaner. A substitute for nature.

Extra gain on one calf pays for two feeders.

Best Feeder Made.
Michigan State Board of Health:—I tried every Calf Feeder I could find, but liked yours best.

Worth $10.00.
George S. Bement, Victor, N. Y.:—I am very much pleased with the Feeder and would not be without it for $10. No trouble, no damning, no milk on your clothes, no trouble to teach the calves to take hold of it, no sucking the cows, and the best of all is that when they get about eight weeks old they don't stop for the nipple but just drink out of the pail.

The Principle is Correct.
Purdue University Agricultural Experiment Station of Indiana, LaFayette, Ind.:—We have been using the Feeder to some extent and it is in constant use at this time and we believe it to be very satisfactory in its work. The principle of Your Feeder, I believe to be the correct one. C. PLUMB, Director.

Advise Stock Raisers to use it.
Maryland Veterinary Hospital:—I am very much pleased with the Feeder and would advise stock raisers not to be without one.

Price $1.50 including two nipples, sent postpaid for $1.75. We guarantee satisfaction, but if you are in doubt about its value we will send one on approval for 50c to cover postage, remainder to be paid if satisfactory. Be Sure and send for our twenty-two reasons why you should use a feeder. It's free. Sold by one dealer in a town.

SEND FOR CATALOGUE NO. 20 We issue a complete illustrated catalogue containing prices of which the above are only a few samples. You ought to have a copy of this book in your home or office and we will send it upon request.

CHICAGO HOUSE WRECKING CO. WEST 35TH AND IRON STREETS, CHICAGO.

CONCERNING OUR ADVERTISERS.

Heebner Threshers and Powers.

Two machines which go hand in hand upon the farm, allowing the owner to do for himself what would cost him a considerable sum if he had to hire, are the Heebner Threshers and Cleaners, and the Level Tread Powers. Both represent high types of usefulness, as well they might, for they have been manufactured by one concern, the Heebners, father and sons, at Lansdale, Pa. for upwards of sixty years. They are the product of a region where people were taught that the surest way to get on in the world was to do for themselves. These machines make that possible. The powers can be put to dozens of different uses on the farm besides threshing. The threshers have a capacity of from 200 to 500 bushels per day. The owner of one easily does his own threshing, and may quickly recover the entire cost by threshing for his neighbors. All grains and grasses are within their compass, and they come from the machine ready for the bin. An advertisement will be found elsewhere in these columns. It should suggest to readers that it is as good a plan to do for one's self, to be independent of the coming of the thresherman and to save where savings can so easily be made.

A Blessing to Dairymen.

Childs' So-Bos So Kilfly proves a most profitable invention. There are numbers of things invented and placed upon the market which although they may have the elements of novelty and possibly prove of some value among certain lines, yet fail to be of really intrinsic value to those for whom they were originally designed. The exception, however, proves the rule, and this has been most prominently shown in the case of Childs' So-Bos-So Kilfly, a preparation for killing flies and insects upon cattle. Ever since its first introduction it has been steadily growing in favor among dairymen and farmers, who have found that under its benign influence, cows protected from the annoyance of flies have actually given about 20% more milk than before. Nor is this all. The comfort of those employed in milking and the saving of time thus affected are prominent among the virtues of So-Bos So. Its perfect antiseptic qualities and absolute harmlessness have commended it for general use in stables, chicken-houses and pig-pens, while for scours in calves, hog cholera or foul in calves' feet, it has been found to be an unequaled preventive. The ease and rapidity with which it may be applied, and the generous terms upon which it is sold, have also proved important factors in establishing its popularity. Many and hearty have been the endorsements given So-Bos-So by leading dairymen all over the country, and Messrs. Chas. H. Childs & Co., of Utica, N. Y., who are the sole manufacturers, are to be congratulated upon having given the dairy industry such a valuable product. They gladly mail full particulars upon request.

Stevens Bros., of Lacona N. Y, write us as follows: "One of the most important of our recent sales of Holsteins was four head to Messrs. Brown Bros., of Lyn, Ont. After spending considerable time in Canada and the leading herds of York State, they made a second visit to Brookside Herd and made their selections. To head their already famous herd they secured the young bull Beryl Wayne's Paul Concordia, and as his name indicates, he combines the blood of the most popular families of today. They also selected the bull calf Sir Mutual Butter Boy to eventually take the place of the above mentioned bull. This youngster was out of Pauline Mutual De Kol and sired by De Kol 2nd's Butter Boy 3d, his dam, De Kol 2d and his sire Manor De Kol, was out of Netherland Hengerveld, official record 26 lbs. 10.6 ozs. butter in 7 days. The females selected by Messrs. Brown were two 2-year-old heifers, Pauline De Kol Bergsma and Sara Jewel Hengerveld, the former due in August by Beryl Wayne's Paul De Kol, the latter dropped a beautiful heifer calf before shipping. She made a tremendous udder and was giving 40 lbs. per day at the time of shipment. She has all indications of equaling her dam, Sara Jewel A. R. O. 21 lbs. 7.9 ozs. butter in 7 days. They are richly bred heifers and are of the right type, and we believe they will be heard from in their new home. Much could be said of their parentage but space will not permit."

Winning Points.

The merits of a thing are usually determined by the number of winning points it may have. The winning points of an oration, for instance, are sound reasoning, good diction and forceful delivery; the winning points of an applicant for a position are ability to work, honesty and faithfulness; and the winning points of a binder are correct principles in construction, durability and ease of operation. One make of machines may have many more winning points than another, just as one man may excel another in mental or physical strength. The vast majority of agriculturists know that the pre-eminence of the McCormick binder is due to the large number of winning points the machine has, among which are its stanch main frame, strong gears, roller clutch, elevator rollers, deck rollers, folding dividers, improved needle and roller twine tension—winning points that have made the McCormick world-renowned.

The many friends of Robert B. Ogilvie, of Wis. will be pleased to know of his election as Vice President of the Zenner Disinfectant Company, the makers of Zenoleum Dip and Disinfectant. Mr. Ogilvie has charge of the Chicago office of that company and is located at 39 Exchange Ave., Union Stock Yards, and will be pleased to see his old friends at any time they are in that vicinity. Any letters addressed to him will also have prompt attention.

Horace L. Bronson of Cortland, N. Y., writes as follows: The demands on the Star Farm Herd, during the past spring, have been so heavy that I have been compelled to replenish my stock and have just purchased from Riverside Stock farms in New Jersey, a carload of the finest heifers that I have been able to find anywhere. These females are bred second to none in the country, and are the finest individuals that I have ever seen. Some of the heifers have been bred and others will be to Mercedes Julip's Pietertje Paul. Believing that the best is the cheapest, I have spared neither pains nor expense to place at the head of Star Farm herd, the son of the 1901 world's champion butter cow, Mercedes Julip's Pietertje and Johanna Rue 2d's Paul De Kol, sire of 10 A. R. daughters with large official butter records, including Witt Duchess with an official 7 day butter record of 24.88 lbs. Some of my recent sales are as follows: To Mr. H. C. Gazlay, of Accord, Ulster County, some elegantly bred cows; in this consignment were Hope Crumhorn 2d, Queen Mechthilde Colantha, Paragon Elez De Kol 2d, Mona Pietertje and two heifer calves, also the splendid yearling bull, Aratsia Koningen. This stock was selected with great care by the purchaser for a foundation herd for his beautiful summer home near the village of Accord.

To Helen M. Westphall, M. D. three elegently bred two-year-old heifers in Paul DeKol Clothilde; Hengerveld Clothilde DeKol; Madge Pauline DeKol; and to head the herd she selected a magnificent young bull, Daisy Pauline Paul Butter King. A sister of this bull recently made in her two year old form an official butter record of 12 lbs. in a week, and her milk averged 4% butter fat during the test. Mr. Charles A. Shults of Freeville, N. Y.; visited Star Farm in April in search of a bull to head his herd. After considering the merits of other animals offered, he settled on Anzaletta Paul DeKol, and I shipped him about four weeks since. This bull is out of Anzaletta Pauline Paul. In her two-year-old form she gave 59 lbs. of milk in 1 day, and some weeks afterwards passed into advanced registry in a butter test conducted by Observer West of Cornell.

One of the finest individual bulls ever shipped from Star Farm herd was Zaverne Paul DeKol, dam Zaverne 3d, and sire Guess Not Paul De Kol. He now heads the herd of Mr. S. H. Cornell. West Haverstraw, N. Y On Tuesday, May 12, 1903, Mr. H. A. Moyer, of Syracuse, N. Y., visited Star Farm. Mr. Moyer wants nothing without it is backed by a dam with an official 7-day butter record of 20 lbs. or better. In the purchase of A. & G. Inka McKinley in Star Farm herd, he has secured a two-year-old heifer whose dam, Segis Inka has an official 7-day butter record at 4 years, 6 months, 12 days of 476⅝ lbs. of milk and 18 lbs. 8.1 oz. butter. In 1901 this famous cow was given another official 7-day butter record test and raised her former 7-day butter record to 23 lbs. 4.4 oz.

Another sale made from Star Farm was to State Hospital at Morganton, North Carolina. They purchased Saladina Pauline, a son of Pauline Paul Sir Mechthilde the fashionably bred cow, Madge P., and the promising cow, Daisy H. Paula; Mr. William Sweetland, of Dryden, purchased the elegantly bred cow, Tena. I should not fail to mention that the enterprising Poultry Fancier and Expert, Mr. Fred H. Rivenburgh of Oneida, N. Y., has determined to enter the Holstein field. I have just shipped to him, four of the best females from the Star Farm herd. Mr. Rivenburgh personally selected the stock with apparently but one consideration in mind, and that was to get the best, regardless of expense. On Wednesday of last week, I shipped to Mr. H. T. Field of Oneida, N. Y., the four months' old bull calf Zo Zo Butter King, dam Lady Zo Zo Pauline, sire Guess Not Paul DeKol.

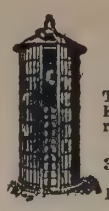
The Case & Walker Sale of Jerseys.

The Case & Walker sale of Jerseys at Rushville, Indiana, April 28th, was an occasion of more than ordinary interest and importance to the dairy interests of the United States. All told, there were ninety-three head sold, practically all of them imported or immediate descendants of imported stock. There were no record-breaking prices obtained, but the average of $210 per head shows a very even lot of cattle and a discriminating attendance of buyers. The highest price realized was for the cow, Golden Fern's Rose Fern, which sold for $700 to Henry West of Scappoose, Oregon. Mr. West was also one of the highest bidders for bulls, paying $400 for Fern's Prize. Mr. A. T. Dempsey, of Ohio, paid the same price for the bull calf, Fern's Sweet Eyes, only fifteen days old. Mr. C. E. Parfet of Golden, Colorado, was one of the heaviest purchasers and was the second highest bidder, paying $670 for the cow, Fabulous Interest.

The detailed report of the sale shows that these cattle were distributed among thirty-nine different buyers in fourteen states. The prices for bulls ranged from $400 down to $60 an average of $177; for bull calves from $400 down to $20, an average of $100. Thirty-six cows ranged in price from $700 to $60, average $297. Heifers brought from $370 to $60, average $176, and heifer calves, any age from eleven months down to two months, sold for from $270 to $55, an average of $145.

It is claimed that these prices did not bring Case & Walker any profit because so many of the animals sold for much less than they cost on the Island, which, whether true or not, is a decided encouragement for breeders and dairymen to attend sales of this character, or to be represented at such sales, where there is always opportunity to buy the highest class stock at reasonable prices, notwithstanding that particular animals may sell for fancy prices.

East Tennessee Farmers' Convention.



The East Tennessee Farmers' Convention, which will meet at Knoxville May 21, 22 and 23, will not only be a notable gathering of the progressive farmers of the state, but will be of unusual value in several unique particulars. At the coming meeting, a new and very valuable feature will be introduced in the demonstration lectures. Professor Shaw of the University of Minnesota, will use a herd of cattle in teaching the farmers the value of conformation as a means of judging stock. Illustrative material will also be used by members of the staff of the Experiment Station in their adresses.

ILLUSTRATION.

New Factory Building Just Purchased by International Stock Food Co., Minneapolis, Minn.

It is the famous Exposition Building built by the city of Minneapolis on the bank of the Mississippi river and overlooking St. Anthony Falls. It is now to be used for the manufacturing of their celebrated "International Stock Food." The building is 300 by 300 feet and has an addition 75 by 150. It is the largest manufacturing building in the entire Northwest and contains over 600,000 feet of space. It cost the city over $400,000.

The railroads have granted a single fare for the meeting, the program is the best offered by the Convention, and it only remains for the farmers themselves, by their presence, to make this the record gathering of this Association.

VETERINARY.

Queries in this department answered by DR. A. H. HARTWIG, Watertown, Wis.

Eating of Placenta.

I would like to know if it is well to allow a sow or a cow to eat her afterbirth. K. A. H.
Maple Valley, Wis.

ANSWER.

There is no danger in allowing the sow to eat her afterbirth as far as the sow is concerned. But it may create an inclination for her to eat the pigs also.

Milk Fever.

I had a cow die of milk fever. She took sick about twenty four hours after calving. She became unable to stay on her feet and fell; she only got up once after falling. I gave her the Schmidt treatment, waited eight hours and gave it again, gave her medicine for her bowels (Epsom salts 1½ lbs.) and also injections, drew her urine, but all to no effect. She died within 38 hours. She had milk fever most assuredly, but what seemed strange hereyes were sensitive to the touch and they should not be that way. R. F. G.
Tulare, Cal.

ANSWER.

You should never attempt to give a physic to a cow with milk fever, as you are sure to kill her if you do. If you will look up the Schmidt treatment as given in the veterinary columns of the DAIRYMAN, you will find that you are especially warned not to give physic.

Bladder Trouble.

I have a mule about 14 years old that bites first one side and then the other and kicks the wall all night with first one foot and then the other, he has beat the hair off one side his hip with his tail. Has frequent actions of urine, 6 or 8 times a day, high color, ropy and offensive odor. His belly is a little large for size of mule. C. C. P.
LaCrosse, Fla.

ANSWER.

It is possible that your mule has one or more stones (calculi) in the bladder, which cause urinary passage to be obstructed to such an extent that he can only pass a small quantity of urine at a time and may also account for the high colored and ropy urine and the intense pain exhibited. This will require a personal examination and treatment by a qualified veterinarian.

Leucorrhoea.

I have a Guernsey cow in high condition, with bowels rather constipated. Calf delivered naturally, afterbirth soon expelled; noticed in a few days a copious discharge; after a time a quantity of pus would slowly come from the vagina "supposed;" used creolin injections in passage; no improvement. By inserting hand found a bloody mucus flow from womb, supposed, and if allowed to remain in passage forms a thick white mucus which may be removed by the hand, or if left alone will be discharged by the cow. H. D. M.
St. Johns, N. B.

ANSWER.

Your cow has leucorrhoea, which may be due to an ulceration of the mucous membrane of either the vagina or the uterus. Flush out these organs with tepid water and ascertain the cause. If the ulcerated surfaces have been located have your veterinarian dust the parts with dry powdered borax once daily, and give iron, arsenic and vegetable bitters internally.

Eruptions on Neck.

Have a cow that is troubled with some eruption, only on neck, multitudinous, minute pimples.
Memphis, Tenn. T. H. W.

ANSWER.

Your description of the case is not sufficient to warrant an intelligent conclusion. Please describe more definitely and we will try to help you out.

Calf Scours Don't let your calves die from this disease. You can save them by using Hood Farm Calf Scour Treatment, which consists of Calf Scour Cure, a liquid preparation which checks the scours, and Digestive Powder, a preparation of pepsin, which aids digestion, creates an appetite and keeps the calf from becoming stunted in growth.

HOOD FARM

Calf Scour Treatment

SAVES THE CALVES.

At Hood Farm, Lowell, Mass., in one year, there were 83 cases of scours. Every calf was treated with these remedies and all but 3 were saved. Formerly we lost 75 per cent. of all calves affected.

Two sizes of each remedy, $1 and $2.50, large contains four times the quantity of the dollar size. Prepaid to any railroad express point in U. S., 25 cents additional.

Address C. I. Hood Co., Lowell, Mass.

"SAVE-THE-HORSE"

—TRADE MARK—

SPAVIN CURE.

POSITIVELY AND PERMANENTLY CURES

Bone or Bog Spavin, Ringbone (except Low Ringbone) Curb, Thoroughpin, Splint, Capped Hock, Shoe Boil, Wind Puff, Weak or Strained Tendons or Lameness.

FROM A REPUTABLE AND NOTED TRAINER

GLENVILLE DRIVING PARK, CLEVELAND, OHIO.

For the enclosed $5.00 please send me one more bottle of "Save-the-Horse." It is doing great work. Respectfully, MILLARD F. SANDERS.

HARTLAND, LIVINGSTON CO., MICH.

Find enclosed money order for $5.00, for which send me another bottle of "Save-the-Horse" spavin cure as it has done all you claim for it for me With the bottle I bought of you I took off a curb, spavin, and a side bone on a 3 year old mare that other spavin cures refused to help in the least. I consider your spavin cure the best on the market. E. M. PARSHALL.

HOWICK, QUEBEC.

I had a mare suffering from a bone spavin and very lame. I concluded to try a bottle of "Save-the-Horse" and at the expiration of six week's treatment she was free from all lameness and I consider it one of the greatest compounds made. DAVID BARRINGTON.

EDGEWATER, N. J.

Enclosed find check for $5.00 for which you will kindly send me by Wells-Fargo Express one bottle of "Save-the-Horse" as soon as possible. The horse I have been treating with "Save-the-Horse" went sound and I sold him. The last I heard from this horse he was still going sound and working every day, and I think he will stay sound. The bottle I am ordering now I will use on another horse that has a pair of spavins and a curb; he does not go very lame, but walks on his toes and I think "Save-the-Horse" will bring him around so that he will walk all right. Very truly. OTTO MEYER.

The fire iron is uncertain and invariably only aggravates the disease or injury; blistering is less effective than the fire iron, and both necessitates laying up the horse from four weeks to two months Arsenic, mercurial and poisonous compounds produce irreparable injury

"Save-the-Horse" eliminates all these factors. Horse can be worked continuously. Cures without scars, blemish, or loss of hair.

It can be applied at any time, anywhere, any place, and in all conditions and extremes of weather—hot or cold. And no matter what the age, condition or development of the case or previous failures in treating, the concentrated penetrating, absorbing power of this remedy is unfailing.

$5.00 PER BOTTLE.

Written guarantee with every bottle constructed solely to satisfy and protect you fully. Need of second bottle is almost improbable, except in rarest of cases. Copy of guarantee sent upon application.

IF YOU HAVE A CASE DIFFERENT FROM INSERTED IN OUR BOOKLET OR ADVERTISING WRITE US.

We will advise you frankly as to the possibility of the remedy effecting a cure. Give explicit particulars, give the veterinary's diagnosis, if he is competent—inform us fully as to the age, development, location of swellings, lameness, action and previous treatment.

$5.00, all druggists and dealers, or sent express prepaid.

TROY CHEMICAL CO., TROY, N. Y.

BLACKLEGOIDS

BEST PREVENTIVE OF BLACKLEG.

Blacklegoids afford the latest and best method of vaccination against blackleg—simplest, safest, surest. They are always ready for use; no filtering, measuring or mixing is necessary. Accuracy of dosage is always assured, because each **Blacklegoid** (or pill) is exactly sufficient for one inoculation. Administration with our Blacklegoid Injector is easy. The operation need not consume one minute. **Blacklegoids** are sold by druggists; *ask for them.*

Our newly printed eight-page folder on the "Cause and Nature of Blackleg" is of interest to stockmen. Write for it; it is free.

Relative Values of Fat in Cream and Milk.

A California Inquiry.

ED. HOARD'S DAIRYMAN:— Enclosed please find money order for two dollars, which will pay my subscription for 1902-3. Your valuable dairy paper has given me knowledge that I believe could not have been gained through any other channel. It certainly has helped to feed and understand how to breed for dairy purposes. I have been dairying with about 20 cows the past two years, and have started. Expect to improve my herd and profits through your paper, and the knowledge I get in reading the experiences of others until I can do much better.

I am now putting in a new DeLaval hand cream separator, so I may have the warm skim milk for the calves. I have delivered the milk the past two years to a creamery about three miles distant. We have no complaint to make of the creamery people, but think the separator will pay anyway. We expect to sell the cream to the same creamery, and, by the way, one question in regard to selling cream. We get 90 cents per hundred for 4% milk when butter is 25 cents per pound, as a basic price. Now if we sell the cream to the same creamery and expect to get the same amount of returns at the end of the month, how should we be paid? If the cream tests 25%, what would each per cent of butter fat be worth per pound or 100 pounds, to bring the same price as the milk does. There is no cream sold to the creamery at present. I have many questions to ask, but will wait till some future time, as I think this is asking too much already. I will send you a record of my herd soon for 1902.

Chino, Cal. A. C. S.

When one receives ninety cents per one-hundred pounds for four per cent milk, he is paid at the rate of twenty-two and one-half cents per pound for the fat; and when he delivers cream, he should be paid on the same basis, or perhaps a little better, if there is enough cream received to make it any object to the factory in reducing their running expenses. The editors of this paper for some years have been delivering cream to the local creamery and they receive the same price per pound of fat as others who deliver whole milk. In a creamery where a large proportion of the patrons delivered cream, the factory would be able to get along with less machinery, they would not be at any loss in separating, and could therefore afford something more for fat in cream than for fat in milk. In other words, while the overrun from the fat in the milk is between 12 and 16 per cent, it is from 16 to 20 per cent from the fat in cream.

Did Corn Silage Cause a Shrinkage in Milk?

North Carolina Inquiries.

ED. HOARD'S DAIRYMAN:—Will you kindly tell me through the columns of your valuable paper what was the trouble with our feeding ensilage? Last summer we built the first and only silo in this immediate section. It is a round, wooden-hoop silo, fourteen feet in diameter and thirty feet deep. We filled it with well eared southern ensilage corn, cut in half-inch lengths. It kept very well, and we began feeding it about Nov. 1st.

Our herd of sixty cows, consisting of thoroughbred Jerseys, grade Jerseys and a few Holsteins, all in different stages of lactation, were then averaging sixteen pounds milk per cow per day. We fed them as follows: Six a. m., 10 lbs. cotton seed hulls, mixed with 3½ lbs. wheat bran and 1½ lbs. cotton seed meal; at 8 a. m., were turned out in lot for exercise and water, and given 8 lbs. pea-vine hay. At 5:30 p. m. were put back in stable and fed 3½ lbs. wheat bran, 1½ lbs. cotton seed meal mixed with all ensilage they would eat through night. Each cow received a spoonful of salt with every feed. These cows steadily decreased in milk until last month they averaged only 11 lbs. per day. Although they look pretty and sleek and possibly a little too fat, they must have suffered some from indigestion, as they wanted to eat sand, rotten wood, etc. We then gave them with each feed of ensilage a spoonful of soda.

Now that our ensilage has been exhausted, we are feeding in its stead only 10 lbs. cotton seed hulls, making daily ration 20 lbs. hulls, 8 lbs. pea-vines, 7 lbs. wheat bran and 3 lbs. cotton seed meal, and although we have been feeding this ration only 7 days, the herd has increased over 25 per cent and is still improving. Of course the above rations were averaged, as fresh cows receive more, and those giving small quantities of milk received very little grain.

In about two weeks we will begin to cut oats and Canada peas and feed green, and at proper time will fill the silo with same. We will have enough of this oat and pea forage to give cows one full feed per day and would thank you to formulate a balanced ration from any or all of the following feed stuffs: Cotton seed hulls, $5 per ton; pea-vine hay, $15; wheat bran, $20; wheat middlings, $21; cotton seed meal, $24; corn meal, $25; corn chops, $20; corn bran, $15; cow peas (ground), $23.

Would like to use as many cotton seed hulls as can profitably, as can get them near-by. A. O. McE.

Wilmington, N. C.

This correspondent makes an apparently strong case against silage, and all the stronger, because when silage was omitted and cotton seed hulls substituted, there was a marked increase in the amount of milk. But this may be only one more of those very numerous cases wherein the real cause is far removed from the apparent cause. The testimony in favor of silage, as a part of the ration for milch cows, is of too long standing and too voluminous to be over-borne by here and there a case where there was a decrease in milk production while silage formed a part of the ration. We are, therefore, unable to conclude that silage as such had any influence whatever in lessening the milk flow as reported above. We are equally at a loss to suggest any probable cause for the falling off in milk other than possibly, the intermediate indigestion. This, however, was itself a result and not a primary cause, and the subsequent increase in milk flow must have been due, in our opinion, not to the substitution of cotton seed hulls for silage, but to an improved condition in the digestive apparatus of the cows.

Assuming that the cows ate twenty pounds of silage, which is a very moderate estimate, appearances indicate that the cows were over-fed when receiving silage.

Our suggestion for a ration when the oat and pea forage becomes available, is as follows:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients: Protein.	Carbohydrates	Ether Extract
30 lbs. oat and pea fodder	4.80	.54	2.13	.06
8 lbs. cow pea hay	7.14	.86	3.09	.09
4 lbs. corn bran	3.64	.30	2.39	.18
2 lbs. cotton seed meal	1.84	.74	.34	.17
10 lbs. cotton seed hulls	8.89	.03	3.35	.17
Totals	26.31	2.47	11.26	.67

FINE STOCK FARM near pretty village on large lake in Waukesha Co. 181 acres, Excellent soil. Well appointed house, tenant house, good out-buildings, water excellent and plentiful. HILES & MYERS, C-100 Matthews Building, Milwaukee, Wis.

Buy You a Ticket to CROOKSTON, MINN., and call upon
The Polk County Land & Loan Company
For choice Red River Valley Farms. They pay railroad expenses if you buy from them. A few good bargains

360 acre farm, 4½ miles from Crookston, Minn., (a city of 7,000 inhabitants), and 2½ miles from the State Experimental Farm. This is a photograph of the buildings as they are today: House is 16x24 1½ stories with an L 14x22, and a wood shed in connection 20 ft. square, all on a brick foundation. Barn 28x48, with a lean to 16x48, sheeted both inside and out. Two granaries, one 14x80, and the other 14x42. The buildings are all well painted and in very good repair, and has a fine artesian well. Every acre of this farm in under a high state of cultivation, and is well drained by a slight ravine running through the farm, merely sufficient for self drainage. The soil is a rich deep black loam with a clay sub-soil, and in every respect is considered to be one of the best farms in that vicinity. Our price on this farm is $35.00 per acre.

This is a **320** acre farm about 2½ miles south of the city, this farm is quite well improved, has a very good house of about seven rooms, 1½ stories, barn large enough for ten head of horses, also a good granary, pasture and an artesian well, also has a good well at the house, good grove around the building. This is a very choice piece of land for the price $32.50,

160 acres north-east of the city; this is all hay land, and located in a German settlement, the surrounding country is nearly all under cultivation; we consider this a good piece of land for an investment, this could all be put under the plow, if desired, Price $19.00 per acre.

226 Rialto Bldg., San Francisco, Cal.

Fine Dairy Farm for Sale.
Near St. Paul, Minn. 210 acres good land with ample buildings of all kinds. Page fence, cedar posts. Pure bred Holstein cattle and Yorkshire swine sell readily at good prices. Good markets for all dairy products. Will sell with or without stock and other personal property. Easy terms. Enforced removal to California only reason for selling. T. S. TOMPKINS, Pasadena, Cal.

Official Records of Holstein-Friesian Cows from March 14 to April 18, 1903.

This class of records are made under the supervision of agricultural colleges and state experiment stations. In every case a representative of such an institution, paid by the institution, oversees the entire work. The samples of milk are tested by him in duplicate and a composite sample is forwarded by him to the station or college to be tested there. In cases of phenomenal production re-tests are also made during which the cows are constantly watched that by no possibility the contents of their udders can be affected by the injection of milk or fat.

During this period reports of 95 cows have been received:—one has a sixty-day record, six have thirty-day records, four have twenty one day records, five have fourteen-day records, and all but one have seven-day records;

Sadie Vale Concordia 32258—in 60 days, milk 5063.6 lbs., fat 176.420 lbs.: in 30 days, milk 2752.6 lbs., fat 98.937 lbs. Owner, McAdam & VonHeyne, Deansboro, N. Y.

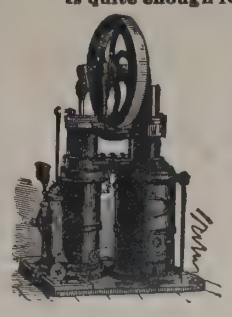
Soy Beans as a Forage and Seed Producing Crop.

The soy bean is a native of China, where it is said to yet grow wild and forms an essential part of the food for the inhabitants. It was early introduced into Japan, where it derived its name and is used there principally as a human food.

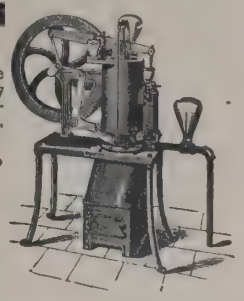
Professor Georgeson, of the Kansas Station, was largely instrumental in securing seed and getting the plant established in the United States at an early date. The United States Department of Agriculture has in recent years secured choice samples of seed from Japan and sent them to various stations to be tested.



The writer received his first supply from the United States Department of Agriculture in 1899 and grew them on the station farm successfully the season of 1900. No extended effort has been made to grow soy beans in the north until quite recently, many farmers thinking it impossible to grow the plant except in the extreme south, where it had become acclimated.

At the Wisconsin Station during the past season, experiments were carried on with eight different varieties, all of which did well and gave yields ranging from fourteen to thirty-eight bushels of dry beans per acre.

The different varieties of soy beans



HALF ENOUGH WATER

Is quite enough for some people, but most people want water every day. If

RIDER or ERICSSON HOT AIR PUMPS

Are used you can have water every day in the year, and your cook or stable boy is the only engineer needed. 25,000 in daily use. Catalogue "B 5" on application to nearest store.

tested on the experimental plots, with yield of dry beans per acre and other data, is given in the following table:

NAME OF VARIETY.	Growing Period.	Yield per acre in bu.	Weight per measured bushel.
Ito San	136 days	33.7	56
Early Brown	136 days	16.5	56
Med. Early Black	133 days	14.3	54.5
Med. Early Green	155 days	22.3	56
Med. Early Yellow	136 days	39	54
Michigan Green	162 days	26.7	58
Wisconsin Black	122 days	23	54.5
Early Black	133 days	17.3	52

The soy bean belongs to the great family of plants known as leguminosae and, through the action of certain micro-organisms which grow in nodules on the roots of the plant, has the power of taking free nitrogen from the air which is stored in the plant and gradually enriches the soil on which it is grown.

It is also a great drought resisting plant and seems to flourish during the dry, hot summer months, when other plants are suffering exceedingly for moisture.

The soy bean is not used extensively as a human food in the United States, its chief use being that of a forage plant and a soil renovator. More should be known of this plant, as the protein content is so high compared with other feeds that it commends itself readily to dairymen and stockmen who desire protein feeds to use in balancing the ration fed to farm animals.

METHOD OF GROWING.

If the desire is to grow the soy bean for seed, plant in drills about thirty inches between the rows, dropping the beans about four or fine inches apart in the rows. About one and one-half or two pecks of seed per acre will be neccessary when so planted. A common grain drill can be used, stopping the intermediate holes so as to have the beans the proper distance apart. A corn planter can also be used, but as a rule the rows are a little too far apart and the yield of beans will not be so great per acre, although the quality will be better. The time for planting is the same as that for corn and the ground can be prepared in the same way. The beans will not stand dragging after above ground, as they break off readily, therefore they should be cultivated between the rows instead. Two or three cultivations are all that is necessary, as the broad flat leaves cover the ground so completely that weeds are soon smothered.

The light, well drained soils seem best adapted for the growth of soy beans and it is said to grow on sandy land too poor to grown corn. On all soils it will not readily develop nodules on the roots which contain the bacteria that aid in appropriating nitrogen from the air.

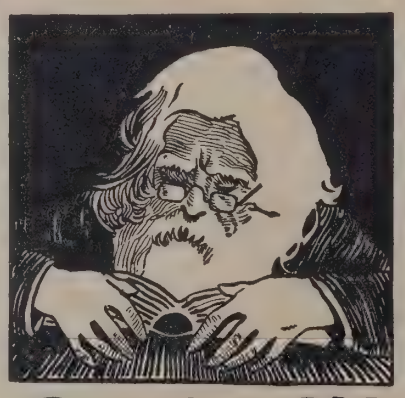
In some instances where nodules do not develop the first season, if the same plot of land is planted the second season to soy beans, the nodules readily develop. In other sections the ground must be inoculated with soy bean bacteria before the nodules develop. This can be done by securing ground from a plot that had previously grown soy beans on which the nodules developed readily, and scattering it previous to planting on the plot of ground which is desired to grow the crops. Where this is done the plot should be harrowed after scattering the bacteria laden ground.

From the experience of Professors Emery and Kilgore, of the North Carolina Experiment Station, soy beans make a high grade ensilage for dairy cows, which was fed with entire satisfaction For dairymen that have silos, it seems that high grade silage could be obtained by planting the soy beans with the corn, using in the planter about one-fourth soy beans to three-fourths corn and planting in drills. The Medium Green variety would be best suited to the so-called corn belt and the Ito San, which is an earlier variety, in that portion north of the corn belt proper.

Soy beans and corn were grown by members of the Wisconsin Experimental Association during the past season in accordance with the method described above, and no difficulty was experienced in cutting and binding with the corn harvester.

Soy beans make a good hog pasture, and pigs take to the beans quite readily after becoming accustomed to them. The pigs should be turned in at the time the beans are fully developed and will harvest them to advantage, converting the soy beans into pork.

A plot was sown to soy beans and rape at the Experiment Farm the past season for the purpose of producing a hog pasture, but the rape matured much earlier than the beans and was past the feeding stage when the beans matured sufficiently to pasture. This experience leads the writer to believe a good hog pasture could be secured by planting soy beans, with corn planter in drills three and one-half feet between the rows and sowing rape between the rows at the time of the last cultivation. The rape would make considerable growth by the time the beans were sufficiently matured, thus affording an ideal hog pasture.



Growing soy beans is yet in the experimental stage in Wisconsin and we have much to learn in the way of securing proper varieties, adapting them to our varied conditions, in methods of planting, harvesting, threshing and converting them into the most valuable stock food. We have thus far demonstrated that they can be grown for hay, a soiling crop and for seed in Wisconsin, and we trust from the experience of the many members of the Wisconsin Experimental Association, who will grow soy beans this year to be able another year to clear up many things that are now somewhat uncertain regarding soy bean culture.—R. A. MOORE, in *Farm Economy*.

Quality of Alfalfa Seed.

ED. HOARD'S DAIRYMAN:—Permit me to call the attention of your readers to the fact that it is known that some of the recent importations of alfalfa seed from Europe are of very poor quality. It seems that some seedsmen are mixing this poor seed with a better grade of seed. In view of these facts, I wish to suggest to your readers that in case they purchase alfalfa seed, they send a sample of a few ounces to the Seed Laboratory of the Department of Agriculture and have it tested. This will cost them nothing and may result in saving them from financial loss.

It is very unfortunate that just at the time when alfalfa is beginning to be appreciated by the farmers of the eastern half of the United States that a bad lot of seed should be imported and thus give this crop a bad name amongst those who are not familiar with it.

W. J. SPILLMAN, Agrostologist.
U. S. Department of Agriculture.

Growing Old

Ought not to mean growing weak and feeble. It does not mean weakness or feebleness for those who eat with good appetite and sound digestion. It is of the utmost importance that old people should retain the power to digest and assimilate food which is the sole source of physical strength. When age brings feebleness it is generally because of the failure to assimilate the nutrition contained in food.

Dr. Pierce's Golden Medical Discovery cures diseases of the stomach and other organs of digestion and enables the perfect digestion and assimilation of food. It invigorates the liver and promotes general physical well being.

"It is with gratitude we acknowledge what Dr. Pierce's medicine has done for grandmother's good, in fact it has cured her," writes Miss Carrie Ranker, of Perrysburg, Ohio. "She had doctored with several physicians but found no relief until Dr. Pierce advised her what to do. She has taken only three bottles of 'Golden Medical Discovery' and is entirely well. She suffered with pain in kidneys, bladder and liver for ten years, and her limbs were swelled, with dropsy so bad she could hardly walk. My grandmother's name is Mrs. Caroline Hennen, her age is 71 years. I will gladly answer all letters of inquiry."

Sick people are invited to consult Dr. R. V. Pierce by letter, *free*. All correspondence is held as strictly private and sacredly confidential.

Dr. Pierce's Pleasant Pellets regulate the bowels.

ARMOUR'S BLOOD MEAL Cures Scours in Calves.

First proved by the Kansas Agricultural Experiment Station, and since corroborated by thousands of leading stockmen who have used it without a single failure. Equally effective for the diarrhea of all animals.

PREVENTS weak bones, paralysis of the hind legs and "thumps" in pigs; "big head" of foals; "rickets" of all young animals; abortion due to incomplete nutrition, and a host of other troubles.

A Potent Food for Work Horses, Dairy Cows, Poultry.

Write us for booklet giving valuable information about **Blood Meal** and our other feeding products. Consult us free of charge regarding stock diseases.

Flavor

The market value of butter is unquestionably its flavor, and its flavor is unquestionably affected by the quality of the salt used. Prize winning butter makers always use DIAMOND CRYSTAL SALT—"*the Salt that's ALL Salt*"—to insure that *winning flavor*. Its pure, dry flakes quickly dissolve—assimilate *evenly* through the butter, and add a keeping quality that is inestimable. No waste—no grit—no mottled effect. The only salt in the world that's all salt. Dairymen will find our illustrated booklet "Just Salt" contains valuable hints. We send it free.

ELECTRIC

Handy Farm Wagons

make the work easier for both the man and team. The tires being wide they do not cut into the ground; the labor of loading is reduced many times, because of the short lift. They are equipped with our famous **Electric Steel Wheels**, either straight or stagger spokes. Wheels any height from 24 to 60 inches. White hickory axles, steel hounds. Guaranteed to carry 4000 lbs. Why not get started right by putting in one of these wagons. We make our steel wheels to fit any wagon. Write for the catalog. It is free.

ELECTRIC WHEEL CO., BOX 130, QUINCY, ILL.

Shoo-Fly THE ANIMALS' FRIEND

Kills every fly it strikes: keeps off the rest. Harmless to man or beast.

Trade Mark

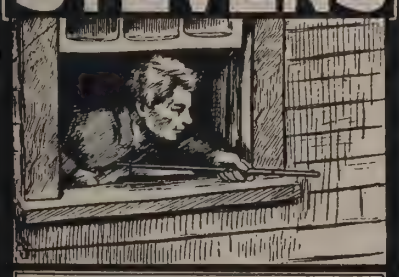
This cow was a terror to milk prior to using ½ cents worth of **Shoo-Fly**. Had it been used earlier, she would not have lost milk and flesh to the amount of $14.00. The other cow was protected early and continued to give 18 qts. of milk daily through fly-time

Shoo-Fly is the original stock protector used by the same dairy-men since 1885, after testing imitations. It prevents contagious abortion and other diseases, cures all sores, scratches, skin diseases, hoof ailments, etc. **NO LICE** in poultry house or any place it is sprayed. Beware of imitations that last only a few hours and make sores. If your dealer does not keep **Shoo-Fly** (made in Philadelphia, Pa.,) send us $1.00 for latest Improved Three Tube Sprayer and enough **Shoo-Fly** to protect 200 cows. Cash returned if cows are not protected.

SHOO-FLY MF'G. CO. 1005 Fairmount Ave., Phila., Pa.
EDITOR knows from experience **Shoo-Fly** is O. K.

CHILD'S **SO-BOS-SO** TRADE KILFLY MARK

MORE MILK MORE MONEY! Cows will give 15 to 20 per cent more milk if protected from the torture of flies with



CHILD'S SO-BOS-SO KILFLY.

Kills flies and all insects; protects horses as well as cows. Perfectly harmless to man and beast Rapidly applied with **Child's Electric Sprayer.** 30 to 50 cows sprayed in a few minutes. A true antiseptic; keeps stables, chicken houses, pig pens in a perfectly sanitary condition.

Ask for Child's SO-BOS-SO or send $2 for 1-gal. can and Sprayer complete, Ex. pd. any point east of the Mississippi.

CHILLS ILLS AND DOCTORS' BILLS **Painkiller** PERRY DAVIS' CURES THEM ALL

Economy in the Use of Fertilizers for Tobacco.

That different soils require different fertilizers is very forcibly illustrated by the experience of Mr. K. H. Teisberg, of Nora, Wis.; and goes to prove that we should study our soil to know its requirements quite as much as we study our crops, if we would produce these crops with the greatest economy.

Mr. Teisberg's land is rather poor, ordinary prairie land, and last year he made some interesting experiments to test the needs of his soil for tobacco, and the results reached were as follows:

"On plot No. 1, where no fertilizers was used, the yield was 1,065 lbs. per acre. Plot No. 2 was fertilized with 600 lbs. acid phosphate, 180 lbs. nitrate of soda and 120 lbs. of sulphate of potash. The yield was 1,494 lbs. per acre—a gain of 429 lbs. over the unfertilized plot. On plot No. 3 600 lbs. acid phosphate and 180 lbs. of nitrate of soda were applied; the yield was 1,191 lbs.—a gain of only 126 lbs. over the unfertilized plot.

From the above we note that the application of 120 lbs. of sulphate of potash made a clear gain of 303 lbs. of tobacco per acre. This shows conclusively that land similar to Mr. Teisberg's is very deficient in potash, and also that an abundant supply of this element is necessary for the production of tobacco.

With regard to his experiments, Mr. Teisberg says: "The ground was plowed in the fall of 1901, and the fertilizer was applied April 24th, 1902, and worked in with a pulverizer. I worked the ground every week until planting time. The tobacco was set June 9th, all the same day. On June 28th, Plot No. 3 was getting ahead, and on July 15th, the tobacco on Plot No. 3 began to bud out, but was somewhat uneven on account of too much rain. Plot No. 2 did not do as well as No. 3 at the start, but did better later on, and the tobacco on plot No. 2 became leafier. The tobacco on plot No. 3 was spindling and the leaves were far between and the fertilizer applied to that plot did not seem to last as long or make the tobacco grow very much except at the very beginning. On plot No. 1 the tobacco lived, but did not seem to grow any for four weeks, and at the end of that time the difference between this and the other two plots was very marked; there being over eight inches difference between it and the fertilized tobacco. On August 6th, I had it photographed, and at that time the two plots of fertilized tobacco were in full bloom, and on that which was not fertilized there was not a sign of bud even.

"On the same date I topped the two fertilized plots. At that time the tobacco on plot No. 3 was just as high but there were fewer leaves and the leaves were narrower than those on plot No. 2. There were more leaves to the stalk on the latter plot, and the tobacco looked splendid. August 20th the tobacco on plots No. 2 and 3 was sheded. The tobacco on plot No. 1, which was not fertilized, was topped on August 25th and sheded September 12th.

"The weather was splendid for curing purposes last fall. The quality of the tobacco from plot No. 3 was good and of medium size, but rather thick, From plot No. 2, quality was splendid in color, large sized and thin, and was by far the best tobacco of the two. In style of quality it was ahead of all the tobacco I grew. The tobacco from plot No. 1 was very small, dark color, and not fit for anything else than fillers. This was a bad year for experiments, as we had too much rain, but the fertilizer shows splendid effects on the tobacco."

From Mr. Teisberg's experience we can see what loss to our crops the absence of any one of the principal elements of plant food may bring about; especially when the soil is already deficient in that element. Ammonia, phosphoric acid and potash are required by all crops, and they can never do their best unless these elements are present in the right proportions. Is it not the part of wisdom for the farmer to find out what his soil and crops require and then see that it is supplied? F. J. MERRIAM.

Quality of Cheese Influenced by Climate.

ED. HOARD'S DAIRYMAN:—Skill and care has a good deal to do with the quality of cheese; likewise its content of fat, but there are some other causes for the frequent variation in quality. Soil and climate have an important bearing, as they control to a large extent the quality of the herbage, and give the conditions for the making and curing of the cheese. Dry, hot climates are not conducive to the making of first-class cheese. The best cheese in the world are made in cool, moist climates, as Scotland, Northern New York, Quebec, a portion of Wisconsin and Eastern Canada, facts which tell very plainly the part played by climate in the quality of the cheese. Another point is that moist, cool climates and sweet succulent herbage, go together, as is shown by the superior quality of the herbage in the countries named.

The character of the herbage has also an important bearing on the flavor of its products. It is well known that the flesh of animals acquires certain characteristics from the feed. The Southdown mutton is fed upon the rich herbage of the hilly, seaside pastures of southern England, and the tender, high flavored meat of the Welch mountain sheep is due more to climate and feed than to breed; the hams of Westphalia, fed upon the mast of the forest, have an agreeable flavor all their own, and the rich, highly flavored animal products fed on the sweet, aromatic grasses of Switzerland, are examples of this fact. Consistently with these analagous facts, it cannot be doubted that the pasture, which is affected by soil and climate, has some effect upon the character of the dairy products. While we grant that the expert and experienced dairyman may make up very largely for all defects in these respects by good culture, fertilizing, and the growth of such crops as will afford every necessary element in the food for production of good milk, still we feel assured, that with cheese, to produce these wholly artificial conditions, will hardly pay. With butter the case is different.

It is wholly artificial, from the fact that, to be at its best, consumption cannot take place soon enough after its manufacture, while with cheese it is not at its best for consumption for several months after it is made, and, during this time, has to run the gauntlet of many extremes of climatic and bacteriological conditions. The very fact that, at the recent National Butter and Cheese Makers meeting, the medal hung between Kansas and Minnesota—two extremes of climate—goes to show, very forcibly, that a good butter is a habitant of no particular latitude or climate.

Fine Cheddar cheese is, therefore, a special product of a favorable locality, soil and pasturage where the climate is both cool and moist. Occasionally we see fine specimens of Cheddar cheese made under wholly different conditions, but these are the exceptions to the rule. These excellent results are only possible at a large cost, which means the creation of a wholy artificial temperature, and, even then, the natural flavored herbage, so desirable, if not indispensable, cannot be obtained artificially, all which goes to show that to make good Cheddar cheese, under unfavorable conditions of climate, calls for a higher price for a product that, after all, would not be as fine as that under more naturally favored auspices.

The fact, further, that we see American Limburger, Edam, Neufchatel, Switzer, Brie, and other special makes of French, Swiss and German cheese, made in various widely distant localities, and in many respects equal to those made in the localities which became famous for these cheeses, proves nothing; the question is, can these various kinds of cheese be made under ordinary conditions and compete with those countries in the open markets.

To manufacture these cheese profitably an artificial market would be required in which the products of these other countries would not compete. Like the corn belt, the cheese belt of North America occupies a geographical and isothermal position all its own. The largest crop of corn ever recorded was not grown in the so-called corn belt, but that does not go to show that localities outside this belt can grow corn as profitably. So with cheese, the fact that even a better cheese

(Continued on page 383.)

If jewelry or anything of delicacy and value is to be cleaned, and you do not know how to do it, just ask one question: will water injure it? If not, you can wash it in Ivory Soap suds. Pure soap and water will make all sorts of dainty things as clean as when new, but be sure that the soap is pure, for uncombined alkali, grease, rosin and the other ingredients of ordinary soaps may do damage.

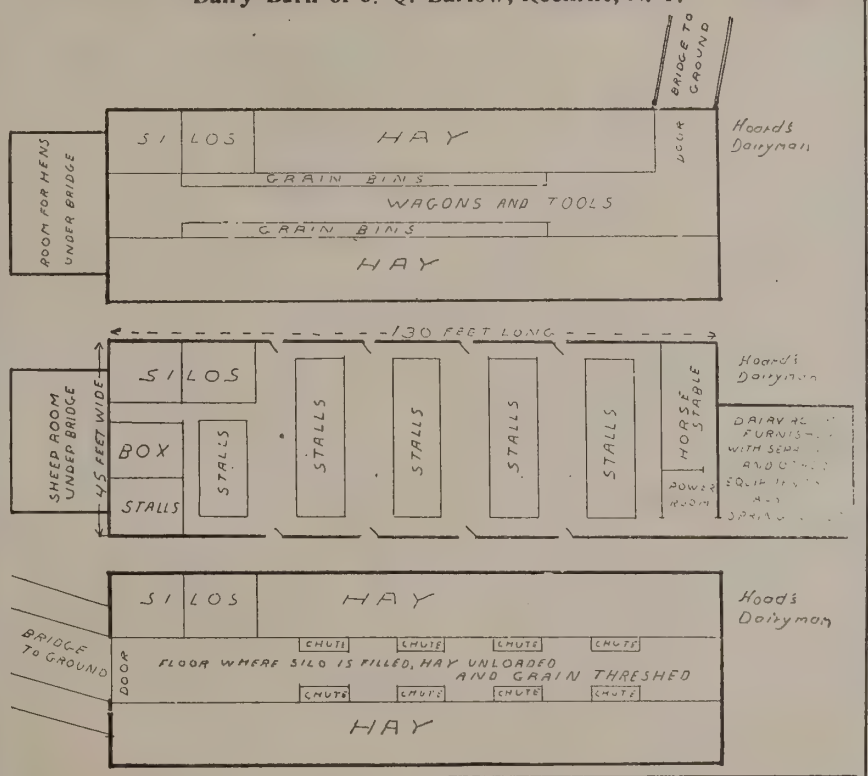
A New York Dairy Barn.

Ed. Hoard's Dairyman:—Some time ago I wrote the description of the dairy farm owned by J. Q. Barlow, Rockrift, N. Y., for the readers of Hoard's Dairyman and promised then I would some time furnish a photo and description of his barn, but have not been able to do so until now. For the comfort of the animals and convenience in caring for them, Mr. Barlow has one of the best barns in the state. All the work of the dairy can be done in this building, for there is a dairy room attached in which there is good spring water, separator, and other equipment for working up the milk. The stable is furnished with the modern stalls, and accommodates, I think, about sixty cows. All the animals on the farm can be kept in this barn, and the arrangement is such that they can be cared for with the greatest economy of labor.

The stable is built with double walls and is very warm. It is also well ventilated. There are driveways between the rows of stalls for hauling out the manure daily, and for drawing in green food for the cows during the summer or fall, as Mr. Barlow practices partial soiling. There are doors at the ends of the four driveways, as shown in the photo, that are made to raise up like a window sash by the use of weights and pulleys. There are two large silos which are filled from the upper floor, and the ensilage is taken out on a truck and run along by the stalls. Chutes, as shown by the cut, deliver hay, straw and coarse feed to either the second or first floor, as is desired. The grain bins are on the second floor along the sides of the bays, where a carload of grain can be unloaded very easily, or grain can be delivered into the bins by chutes from the threshing floor above. Chutes conveniently arranged carry the grain from the bins to the stable below, when it is wanted for the live stock.



The barn is built in the best way throughout, good pine lumber being used. A part of the sides are shingled and the roof is slate. Some of the rooms are ceiled on the inside. Adjoining, or over the dairy room, there are toilet or wash rooms, and rooms which can be used for bed rooms for the hired men, if they are wanted for this purpose. The dairy room is heated in the winter and all the milk work, as washing cans and other utensils, is all done in it, so all the operations connected with the dairy are carried on here. All the work can be done with the greatest comfort possible, and when it is done the dairyman can take off his overalls and blouse, wash up and go to the house, and carry with him nothing connected with his business, the same as a workman goes home from the factory and leaves his work, and do no part of it in the house. The barn, built in the way Mr. Barlow has built it, cost about $6,000.

Report on the Third Educational Butter Test at Chicago.

Mr. E. Sudendorf sends the following report of the butter export:

The scoring of butter at the third test was completed last Thursday, the 7th, and I am glad to report that there has been a gradual improvement in the quality so far as workmanship is concerned, and I believe as soon as conditions are more favorable most of those who are in the tests will make a good quality of butter.

Only a few were scored off on workmanship at the last scoring, while at the May scoring last year, I believe about twenty-five per cent of the exhibits were defective in either grain, color or salt; hence, the progress has been rapid and proves the value of such tests. However, I realize one thing, that only the best butter makers take part in such an educational test, at least that was true at the twelve month's contest conducted in this state last year, and at the last six month's test conducted by the National Creamery Buttermakers' Association. A large number of participants in the present test are first-class butter makers and as a rule know whether their butter will score high or low, and also know the cause of the defects: so from an educational standpoint they do not derive as much benefit as those with less experience would, were they in the test. How to induce those with a limited knowledge of the creamery business to take part in such tests which are conducted for their special benefit, is a problem which I would like to have some one solve.

There were some defects in the butter at the last test which were very common. The flavor of old milk was quite pronounced in most all exhibits, and may only be overcome by having the milk delivered every day. The old cream flavor was very much in evidence, and butter makers receiving cream, scored lower than those who had whole milk to work with. There is only one thing I can suggest to those who have to contend with cream, that it shall be delivered as often as milk is, every day from the first of May until the first of October, and every other day from that time until the first of May, besides properly aerating and cooling of same.

There were not quite as many packages of pasteurized cream butter as at the March scoring, when several attempted to pasteurize in a common vat and did rather a poor job, but there were two tubs of purported pasteurized cream butter, which did not show the effects of pasteurization at all, and if heated to the pasteurizing temperatures at all, the heating was not uniform.

Bacteriologists tell us that a temperature of 140 to 145° F., is sufficient for buttermaking, but I believe that a temperature of 185° will give better results, providing the pasteurizing is done by a machine that will not give the cream a burnt flavor at that high temperature. I understand that in Denmark the cream is heated from 185 to 190°.

Some of the tubs were unclean, finger marks and daubs of butter color were visible, and in most cases such tubs contained poor butter. It may be said that a person can tell the kind of a butter maker who made the butter by the looks of the tub; at any rate the appearance of the tub has its effect on the judge.

The surface of the butter in a tub may be kept smooth by cutting the butter with a wire, a thread or a stick and set away until the butter becomes firm before putting on the cloth and salt. If the cloth is put on before the butter becomes firm, the impression of the cloth will make a rough surface.

I believe there were less over-ripe starters used in the butter at this than at any previous test, but there were indications of off flavored starters, and butter makers should carry two or three starters. Some may be propagated day after day in one-gallon jars the same as the large starter. By having two or more starters a butter maker can always make comparisons, and will soon be able to judge or score the starters and know whether or not they are good, and why. There were quite a number who did not use any starter, and only two of those, as near as I can recollect, scored fairly well, again proving that a good starter is necessary, and every butter maker should strive to use a good one, and use it right. The quality of a starter largely depends upon the care it is given by the butter maker.

A large per cent of the butter had a burnt or curdy flavor, part of which I believe was due to the burnt odor left in the cans from heated skim milk.

Some of the butter had a woody flavor, which in some cases I believe was due to the tubs not being soaked, or not properly soaked.

There was less rancid and less overworked butter than at former tests. Overworked butter usually becomes rancid in a short time. A butter maker wrote me after the February test, when his butter was worked too dry, that he was under the impression that the less water in butter the better. From the analyses made of butter at the Minnesota twelve months' contest, it appears that the samples which contained about twelve per cent water kept the longest, and that which was overworked and only contained eight per cent water became rancid.

The butter at this, the same as at all former tests, which was mild, clean and sweet, scored the highest. What I mean by mild, is the aroma or sometimes called nose flavor, was not high on account of the low per cent of acidity in the cream. About all the high scoring butter was made from cream ripened from 31 to 34 c. c. acidity Mann's acid test, or less than six tenths of one per cent of acidity.

The butter makers may congratulate themselves upon having such a competent judge as W. D Collyer to do the scoring at these tests; he prefers the mild, sweet, clean flavored butter, not because that is a hobby of his, but because of his long experience and study of these questions he has found that kind of butter will keep its flavor longer than that made from cream ripened to a high degree of acidity which will have a high aroma, but will soon lose both aroma and flavor, while the butter made from cream ripened to a low degree of acidity will not change much for several weeks, if made right otherwise.

Butter for cold storage should be made just the reverse. It should be made from cream ripened high, the more acidity the better; a sour starter such as buttermilk will make good butter for cold storage. Sour butter will come out of the freezers sweet, and sweet butter when put into storage will come out fishy. I have no theory to offer at this time why this is true, but know it to be a fact, and would like to see some professors carry on experiments to ascertain to what extent this is true, and why.

The price depends on the quality, and butter makers who expect to get fancy prices for their butter, must make an article that will reach the consumers in good condition. A few of the things to be guarded against, the next few weeks, are soft, slushy butter, un-uniform color, and over-ripe cream, as well as over-ripe starters.

Chicago, Ill.

Note and Comment.

Conformation, Milk and Beef.

Ed. Hoard's Dairyman:—For several years I have been a reader of Hoard's Dairyman, and know not a few of its staff and contributors as well, and had supposed that I was quite well rooted

and grounded in dairy doctrine, and in fact had rather accepted the Senior Editor as being authority on special dairy law and practice, and have even quoted him in confirmation of some passing remarks I have made in public. I am now in great perplexity! At times I am fearful that some of the things I have hoarded up will not stand the X-ray search light of some of our later-day dairy teachers, or rather enlighteners.

In reading a late farm paper, a special dairy number, I soon came across several things that I desire the Senior Editor to harmonize with the "apparent spirit of the present age." The first thing that "struck the eye," was this, fornenst the dairy form:

"For a number of years we have heard considerable about the "dairy form" in cows. Men have deluded themselves into thinking that they can tell what a cow will do at the pail by looking on the outside. This belief doubtless arose from the fact that it is possible by outside appearances to tell quite closely what the carcass of an animal is likely to be. In the case of the dairy cow, however, we have a much more complicated problem, as the secretion of milk is a hidden process."

If this is so, then after this, when I want cows, I will send the hired man to purchase them, and believe the western authority who is recently reported to have said, that "any heifer calf, if rightly grown and fed as a cow should be, will make 300 lbs. of butter in a year."

The next item was altogether more so, as it shifted a good deal of responsibility upon the cow, and refutes all the talk the editor and myself recently heard, that dairy quality is largely the influence of the sire. This paragraph laid it down as settled that for the production of milk through breeding to:

"Select a bull of good Short-horn character, and of good beef type, whose maternal ancestors have proven themselves good milkers, and success is very easy. I would select a bull from a cow with a decidedly feminine appearance in preference to one of more masculine type, and expect better results in the dairy, and I would do the very same if I had beef in view as the most important object."

The concluding pause seems to convey the idea that you make sure of the rabbit as "you get him going or coming." Of course this puts out of controversy any farther mention of the Ayrshires, Holsteins, Jerseys, Red Polls, Guernseys, Herefords, and Black Polls as dairy cattle, and simplifies dairying a good deal, by this our only breed that gets milk with a beef type, and beef with a milk type parentage.

Another item may possibly provoke a little surprise and shows at the same time the absurdity of striving after rich milk, as this excess of fat is worthless so far as adding value to the milk, as this clipping shows:

"The fact is that the nutritive value of milk is largely derived from its solids not fat, and that a milk abnormally rich in butter fat is not the best for general use. Milk testing from 3 5 to 4 per cent fat is, I believe, a better all round milk than one showing a higher percentage of fat."

Still another paragraph that had to do with the kind of milk cheese makers needed to get the largest amount of cheese from was a withering blow to Dr. Van Slyke and the Wisconsin Dairy School, and knocks to smithereens their statements that the amount of fat milk carries determines the amount of cheese it will make. Before me is the report of the Geneva Dairy School expert who shows that 100 lbs. of 3 per cent milk made 8.67 lbs. cheese, and 100 lbs. of 4 per cent milk made 10.80 lbs., and 100 lbs. of 5 per cent milk made 12.60 lbs., each cheese carrying 37 per cent of water, and this in the face of the fact that this dairy special writer in good sized type says that:

"The richer milk is no better for cheese making, as cheese makers are unable to extract all the fat from milk testing over 4 per cent fat."

This will be a surprise to Geo. A. Smith, who asserts that he can incorporate all of the fat of 5 per cent milk into cheese and hold it into .25 of 1 per cent. It would be pertinent to inquire what these experts are incorporating in their cheese in place of the fat they cannot extract from the over 4 per cent milk.

We hardly know whether the writer of another paragraph really intended to make this assertion as broad as it reads or not, but on the face of it, it looks as if breed registration would have to go, and Sol. Hoxie would need to drop color and pedigree, and confine his registry to wash tub measurement, as instance this excerpt:

"A man who has common stock wishes to improve them and purchases a registered animal, or possibly several. He expects great results. He compares them with his common cows and finds that in many cases they are inferior in milk or butter production. The only remedy for this is to base the registration of dairy cattle upon performance, and not upon form and pedigree, as we understand it at present."

Of course dairying as practiced in different sections is somewhat varied, and the Iowa plan is guaged on different lines from the Ft. Atkinson policy, and each of these sections has its organ that tells with no uncertain sound, what kind of a cow is the most profitable and on what lines she is to be built, perform and what to look for in the way of profits, so we reprint the following, which should put the question of finding the cow the farmer needs, out of the controversy as, "She are found," as the clipping will show.

"For the general farmer, or milk shipping dairyman, there certainly is room for a dual purpose cow, one of a cross between the large framed, strong-constituted beef breed and the more highly developed milk producers; a cow that will weigh ten to twelve hundred pounds, with capacity to assimilate food enough to give 5½ to 6 gallons of 4 per cent milk per day and that will drop a calf weighing from 150 to 175 pounds at four weeks of age. A cow of that description, if she does take on too much flesh for the dairy, can go to the block with profit at any time, and her sons will make profitable feeders, and a quality of steak fit for the gods."

All that is lacking in this brief description to the path of dairy prosperity is a few minor details, which might be designated as the key to success. For instance what "large-framed beef-constituted breed" is to be crossed with, and what breed again, are these developed milk producers. It is, or would be highly profitable to have the progenitors of this cross located, so we all can breed large cows that weigh 1,200 lbs. and give 6 gallons, 51 lbs. a day of milk, 10 months in the year, 15,810 lbs. of 4 per cent milk, 722 lbs. of market butter, and drop a 175 pound calf "four weeks old."

Why is this "if" put into this cow's probabilities, if she can do these things and her breeding is easy? Why will she have to take on flesh if she gives the butter fat for 722 lbs. of butter in a year? Why need to go to the block and take her sons with her to "make steak for the gods?"

Will the Senior Editor of the DAIRYMAN please take his "nervous theory, strong developed spine, high pelvic arch, and incurving thighs" and make a bonfire of them, and from its light give us some 20th Century dairying that conforms to every man's belief and notion, and at the same time make the distinctions so clear, that a man could tell whether he was dairying with cows or steers!

JOHN GOULD.

Ohio.

Milk Received at Cheese Factories, As it Is, and as it Should be.

[From Report of Cheese Instructor, G. H. Barr to the Dairymen's Association of Western Ontario.

As it is. There is being delivered at our cheese factories during the summer months very large quantities of gassy, tainted and over-ripe milk. Just what the loss is from this kind of milk is difficult to estimate. It looks as if we might lose our reputation in the English market from this cause, which would be a serious thing, and something we must guard very carefully. But when we consider the actual loss the patrons of cheese factories are sustaining by delivering such milk, and having it manufactured into cheese, it is a serious matter, and one which patrons would do well to look into. In October last, one of the factories I visited was getting about 5,600 lbs. of milk, one vat, daily. On the 8th there were made seven full-sized cheese, and one about 50 lbs. On the

HOME-MADE SOAP

Ten pounds of the best hard soap or twenty gallons of soft soap costs just this, nothing more:

Ten minutes, almost no trouble at all, the grease or fat that you often pour down your kitchen sink (stopping up the pipes) and a can of

Banner Lye

obtainable at your grocer's for ten cents.

It is pure soap—not soap adulterated with rosin, lime clay, or other things that turn your clothes yellow or wear them out.

The New Cleanliness

Soap will take away the dirt that you see, but not the dirt that you can't see. Nothing is sure to take away this dirt but *Banner Lye*. Use it in your

It is an enlarged reproduction from the figure in the center of our trade mark. We make it this size so that you may take in all the lines and remember the figure. It stands for the highest quality of parchment paper on earth. When you buy anything of this kind you should insist that the "Parchment Paper Man" trade mark is on it. It is a positive guaranty of quality.

Pioneer Brand
Parchment Paper

is more largely used than all others by the dairymen and creamerymen of the country. This is so because after trial they have found it the best. They have found that it protects their butter and hence their reputation. It keeps out entirely all destructive germs and vile taints and odors and preserves the sweetness and flavor perfectly. We print your name, cut of dairy or creamery, trade mark or private brand upon each sheet. Send for sample sheets of the paper and booklets. Be sure to ask specially for our booklet, "Better Butter." We mail all these free. Address

THE PATERSON PARCHMENT PAPER CO., No. 87 8th Street, PASSAIC, N. J

9th, one of the milk wagons was about 1 hour late, and the whole vat of milk got over-ripe; there were only seven cheese made from this milk. The day following there were seven full-sized cheese and a 50 lb. one. The loss from 5,600 lbs. of milk was about 50 lbs. of cheese, which would mean a loss of about $5.50, or about 550 lbs. of milk, about the quantity 22 cows would give—22 cows milked for nothing. In nearly every factory in Ontario there are such losses day after day during the hot weather. The loss from gassy milk is equally as great as from over-ripe. On July 30th one of the factories received 11,234 lbs., equally divided in two vats. One of the vats of milk made a good curd, without any gas. The other was very gassy, nearly a floater. When the two curds were put to press there was about 60 lbs. of curd less from the gassy curd than from the one without gas.

The cheese made from either gassy or over-ripe milk, cannot be fine. They may be made so they will pass inspection in the curing room, but some time later on they will develop an undesirable condition.

Milk may be tainted and not gassy, but the loss in manufacturing is considerable, and it is impossible to make a fine-flavored cheese from tainted milk, and no matter how well a cheese is made, if the flavor is wrong, it is a cull, and must be sold at cull prices. What are the causes of gassy, tainted and over-ripe milk? By the use of curd test and visiting the farms during the past season I was able to get some information on this point. I will give notes taken on a few visits to the farms.

Sample No. 11 made a floating curd in the test. At the farm where the milk was sent from, I found the pails and cans as bright and clean as new. The milk had been strained into the milk can on the stand and thoroughly stirred and aerated there.

The stand was only about twenty feet from the barnyard, a swill barrel was close beside the stand. The buildings around the stand were in such a position that there was very little circulation of air, and of course the more the milk was exposed to such an atmosphere, the more gas germs it would get into it, as the air surrounding such places is full of gas germs.

Sample No 15. A floater, can clean, milk strained, aerated and cooled in water, on grassy plot near the house, but only about twenty feet from where hogs were running. We found even worse conditions than these two cases, but at every farm visited where gassy milk came from, the surroundings were very much the same. The milk kept very close to the hog pen, swill barrel, barnyards, chicken coops or milk yard, and when the milk was removed, it came to the factory in first class condition.

Sample No. 1. Tainted, goosey flavor, no gas; milk not aerated immediately after milking; can very rusty and not clean; surroundings good. Patron got a new can and aerated the milk and it was never found wrong afterwards.

No. 2. Same taint; surroundings good. Whey had been left in the can all day, and the can not washed very clean.

No. 8. Badly tainted and gassy; milk strained and aerated on the milk stand, which was about fifteen feet from a hog trough; can rusty. An old rusty can for whey stood close beside the stand. In this case the conditions are the same as those producing gas, along with rusty can, causing taint.

No. 3. Very bad, goosey taint; can and surroundings clean; milk strained into a can and never touched.

A few taints were found where the food eaten by the cows was the only cause to be seen—rank clover, rape and rag weed. The clover taint did not appear in the cheese to any great extent.

It would appear that taints without gas, come largely from rusty and unclean cans, unclean milking and lack of aeration, and gassy milk is largely caused by the surroundings.

Over-ripe milk, due to the leaving or keeping it at too high a temperature, putting warm morning's milk into the evening's milking.

As it Should Be—It should be from healthy cows, receiving good, wholesome food, pure water; the flanks, udders and teats wiped off clean before milking is commenced; milking with dry hands into clean bright tin pails, never into wooden or galvanized pails, strained (don't forget that) immediately after milking, aerated and cooled at the same time to a temperature of 60°. This must be done in a pure atmosphere, and should be all finished in half an hour after the milking is done. Keep the stable clean or if milking has been done in the same yard for ten years, better change it this year. Keep the pails and cans clean by washing them with a fibre brush and warm water, in which a little sal soda has been dissolved. Scald them thoroughly; remember scalding means using boiling water. This is absolutely necessary to prevent taints. Place the the can on its side in the sun. Scour the cans with salt once a week. Never put milk in a rusty can.

There is a lot of hard labor about milking cows. The profits are none too large. Do not make them less by carelessness and lack of cleanliness. It is a simple matter to produce good milk by doing the work in the right way, at the right time, and in the right place. I trust that every patron who hears this or reads it will examine closely their own farms to see if any of the conditions mentioned are present, and if they are that you will remedy them for your own sake, your neighbor's, your cheesemaker's and for the good reputation of our Canadian cheese.

Comments on the Feeding of the Heifer, Dolly Bloom.

ED. HOARD'S DAIRYMAN: — Noting the record of the Guernsey heifer, Dolly Bloom, also the statement regarding the feeding during the test, it is pleasing to note that the heavy grain ration, usually fed during such tests, was so conspicuous by its absence. The results show conclusively a view always held and practiced by the writer, that the expensive mill feeds are not always condusive to best results, especially to the average dairyman as regards cost of production.

One of the greatest drawbacks to raise the average production per cow is the enormous loss of the very best dairy cows by milk fever, garget and other maladies caused by over feeding too soon after parturition, with the view in mind of getting a good start. And for this reason I would call the attention of every reader of the DAIRYMAN to the cautious feeding during the first month of lactation, by Mr. Lathrop.

Also, another all important question to the dairyman is decided in this record, and that is, practically all the feed used was raised on the farm, thereby eliminating the high price mill stuff.

Mr. Editor, what a factor would alfalfa have been, along with the corn silage!

Lincoln, Neb. J. FRED SCHLEPPI.

"Praise From Sir Rupert."

Hon. A. J. Thynne, of Brisbane, Queensland, Australia in writing a friendly letter to the editor of this paper says:

"There is no dairy farm in Queensland that I know of where the HOARD'S DAIRYMAN has reached without producing useful results in practice, and I wish that more of our people would seek the enlightenment awaiting them in its columns."

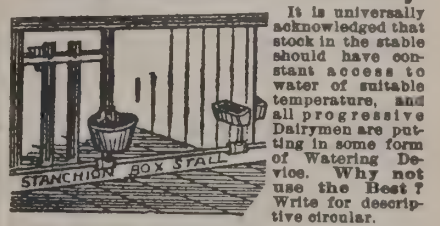
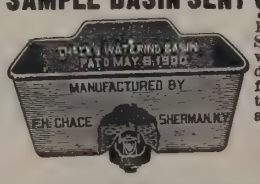
DOCTOR ON FOOD.

Experimented on Himself.

A physician of Galion, O,, says: "For the last few years I have been a sufferer from indigestion and although I have used various remedies and prepared foods with some benefit it was not until I tried Grape-Nute that I was completely cured.



"As a food it is pleasant and agreeable, very nutritious and is digested and assimilated with very little effort on the part of the digestive organs. As a nerve food and restorer it has no equal and as such is especially adapted to students and other brain workers. It contains the elements necessary for the building of nerve tissue and by so doing maintains an equilibrium of waste and repair.



"It also enriches the blood by giving an increased number of red blood corpuscles and in this way strengthens all the organs, providing a vital fluid made more nearly perfect. I take great pleasure in recommending its use to my patients for I value it as a food and know it will benefit all who use it." Name furnished by Postum Co., Battle Creek, Mich.

WILL IT PAY YOU TO TAKE HOARD'S DAIRYMAN?

W. H. Jenkins took a census in 1901 of 50 farmers who were patrons of the creamery in Montrose, Pa. Twenty-five of them read dairy papers; twenty-five did not. The twenty-five who did read dairy papers averaged $50.23 per cow for the year. The twenty-five who did not read averaged $32.95. Here is a difference of $17.28 per cow. Did it pay the twenty-five to read? Did it pay the other twenty-five not to read? That's not all. Those who did read averaged a profit over cost of food of $15.06 per cow. Those who did not read averaged a profit of 66 cents. Is not that dairy farmer standing greatly in his own light who will not pay 2 cents a week for Hoard's Dairyman? These are hard facts worth thinking over.

MUCH IN LITTLE.

In forwarding the subscription of a neighbor, Mr. D. N. Hills, the noted breeder of the Improved Yorkshire hogs, Gambier, Ohio, says:

"It is a great work you are doing, and as one of your readers I feel every week a sense of real obligation to you."

HOARD'S DAIRYMAN started out several years ago with the idea that there was a great deal to be found out and learned in this business of dairying. The paper has been hailed as a friend and helper by nearly 40,000 earnest, studious dairy farmers scattered all over this continent and in Europe. While there is a vast host of farmers who keep cows, and who think they could not make a penny by learning any more than they know now, still the first class is growing bigger every day, and their brave, good words, like those given by Mr. Hills, bring us much cheer and encouragement.

Fortunate is the lot of the dairy cow that is bred and cared for by men who realize her worth and goodness and understand, the great governing fact that she is a mother, for only by understanding and obeying the laws of motherhood can men hope to make the best profit out of her.

Fortunate, indeed, is the farmer who comes to this business of dairying in an earnest, studious spirit, for unto him will the cow yield most abundantly of the best there is in her motherhood.

SHORT NOTES.

A wise old dairyman was asked how he came to succeed so well with his cows. His answer is worth studying by every man who keeps cows:

"I don't think," he said, "that I had any more wit to begin with than my neighbors. But they stood stock still, and I tried to improve. They would not spend a cent to improve their knowledge of the business or their cows, or their farm or their stables. They thought that was money thrown away. I thought different. They are where they were 30 years ago; no better ideas or cows than they had then. Some men die before their time."

The man who said that, was the late Hiram Smith of Wisconsin. When he said it, his 200-acre farm carried 100 cows, and was producing more milk and cash than any 1,200 acres lying next to him.

Yet his success did not teach those men about him. They were even a good deal more anxious to pick flaws in what he did, and discount it all they could, than they were to learn from him. Wasn't he right in saying, "Some men die before their time?" The great Teacher said: "Unto him that hath shall be given; but from him that hath not shall be taken even that which he has." Good dairy farming demands that the farmer shall keep from mental decay and death.

A PROTEIN TALK.

Bulletin No. 4, Vol. XV, Agricultural Experiment Station of the University of Tennessee, is a record of a co-operative experiment between Prof. Andrew E. Soule, of the Tennessee Station, and S. E. Barnes, of the Bureau of Animal Industry of the United States Department of Agriculture, at Washington.

This bulletin treats upon the following subject: "The Relative Value of Protein in Cotton Seed Meal, Cow Pea Hay and Wheat Bran."

We have not the room to give all that is said on this intensely interesting question, and so will only enumerate the conclusions of the experiment:

1. Cotton seed meal is one of the richest of protein feeds, but it must be fed sparingly, as it has a tendency to produce nervous derangement of the cow's system.

2. Only about half as much food is consumed in making a gallon of milk as in making a pound of butter.

3. The smallest amount of roughage consumed in making a pound of butter was 43.8 pounds, in which 13 pounds of cow pea hay was substituted for four pounds of cotton seed meal.

This was with group 3 of cows. The highest amount of concentrates consumed for a pound of butter was by group 1, which took 9.2 pounds or 3.2 pounds more than group 3, and 5.2 pounds more than in group 2.

This shows that the substitution of pea hay for wheat bran in group 2, and for cotton seed meal in group 3 greatly reduced the cost of concentrates.

4. It was proved by this experiment that one and a quarter pounds of chopped cow pea hay was equal to one pound of bran, and three pounds of the chopped pea hay was equal to one pound of cotton seed meal.

5. Two and a half tons of cow pea hay can be produced on an acre of average southern farm land, at a cost of $12.50. Put in the market baled, it would be worth $25.60. A ton of bran costs $16 or $1.50 less than the farm selling price of two and a half tons of cow pea hay. The cow pea hay would have twice the feeding value of the wheat bran.

6. Measuring by the yield at the Tennessee Station, it would take 1.2 acres of land to produce in cow pea hay the feeding equivalent of a ton of cotton seed meal. The cost of the hay from that amount of ground would be $16, its farm value $21, and its market value $30. But the pea crop would store in the soil 40 pounds of nitrogen worth say $4.00. The only difficulty in the way of making the pea hay a perfect and profitable substitute for the wheat bran and cotton seed meal was in getting the cows to consume enough of it.

This would suggest the use of a small daily ration of the bran or cotton seed meal, and an increased use of the pea hay as far as is possible to induce the cows to consume it.

7. The cheapest gallon of milk was made by a combination of the pea hay and the cotton seed meal. All this is from the southern standpoint. For the northern farmer the nearest we can approach the cow pea is in the production and use of alfalfa.

CARE OF YOUNG STOCK.

One of the most serious faults of the average American farmer is his lack of knowledge and determined purpose in the care of young stock. We judge of a man's understanding of any question, by the way he does his work. Look over the calves at three, six, or twelve months of age in nine out of ten of our American farms. Note their unthrifty, scrawny, ill-fed looks, and then judge what must be the real knowledge of calf raising, possessed by their owners. Some will say that the owners of these calves do not do half as well as they know. In our opinion that is not the fact. The real difficulty is that they do not half know what they ought to know about these things, and consequently their work is half done. They have never resolutely set themselves to work to study what it means to rear a calf well. When a man is thoroughly saturated with the knowledge of a thing it holds him up to better work.

In March last, two men came into this neighborhood looking for grade dairy calves. They were men who knew what they wanted. They purchased seven grade Guernsey heifers dropped last fall, of one man and paid him an average of $24.28 for the lot. At the same time they said they could purchase calves of the same breeding and age of neighboring farmers for $10 to $15 apiece.

What made this difference in price? Simply the way the calves were handled. The seven calves were handled as follows:

(1) They were kept dry and clean with plenty of fresh, dry bedding every day and their quarters were kept well disinfected.

(2) They were fed skim milk, fresh from the separator, after the first 10 days, with a little ground flax seed and blood meal added.

When the milk was fed they were put in stanchions and the milk set before them in pails. Afterward they were given a small feed of oats followed by alfalfa hay. But the great care was to keep them dry and clean. As soon as they were through eating their oats they were let out of the stanchions and ran together loose in the compartment. They were fed milk morning and evening. When sold, they were in fine, clean, thrifty condition but not fat. They consumed apiece in the six months they were kept, about 3,500 pounds of skim milk, a dollar's worth of oats, two dollar's worth of alfalfa hay and flax seed meal, and fifty cents worth of blood meal.

After paying for the oats, hay, flax seed meal and blood meal, $3.50, and allowing $3 for the value of the calf when a week old — the price allowed by calf buyers— we have $17.78 per calf, as pay for 3,500 lbs. of skim milk and the labor.

Twelve calves were kept in the compartment. Does it pay to make a little study of calf life?

If our calves, pigs, colts and poultry are not given the right care and feed the first year of their lives, they get a set-back in growth from which they never recover. The bottom reason for all this poor live stock that floods the country, is a lack of knowledge on the part of our farmers of how to feed and care for the young things.

We are just entering on the fly season. A little time and expense in spraying the calves three times a week, with some of the fly lotions on the market, will help them wonderfully in their growth and thriftiness. There is good money in knowing what ought to be done, knowing it hard, and in doing it. Too many farmers think they can not afford to spend the time necessary to do such work rightly. If they are working for money, here is where they can most surely find it. However, there is no time of year for cheap and effective calf raising like the winter, provided warm quarters are given.

THE IMPORTANCE OF CONFORMING OUR PRODUCT TO THE MARKET DEMAND.

Of all men or classes of men who produce or manufacture something to sell the farmer is the most unyielding and unwilling to meet the demands of the market and the tastes of the consumer. It is hard to say why this is so, unless it be because of his greater isolation and less contact with men. Not long since Prof. Carroll of Ireland was addressing a body of Irish buttermakers at Carlow, once a famous center for the production of the best brands of Irish butter. He said something which bears squarely on the subject of this article. One remark was this: "What is the condition of the industry (the butter industry in Carlow) to-day? It is dead!

If we endeavour to search for the cause of this serious downfall of the butter-making industry in Carlow, we shall find it in the same series of causes that have brought ruin on many other industries. Shortly and plainly stated, we have worked up to the idea that we knew the quality of the butter that people should like better than they did themselves, Practically, we said: "You don't know what good butter is; the butter we send you is infinitely better than what your tastes recognize as the butter you prefer." While we were endeavouring to insist in this direction, the Dane came along, discovered the quality of the butter that was preferred in the London markets, and provided for this demand. Nay, more, the enterprising Scandinavian found out the qualities of butter that are required in the different markets in England, and the varieties of butter that are demanded are made to suit these markets. At the present time, Denmark and Sweden have each a well-paid commissioner in England, who examines at different markets the characteristics of the butter that is required for the districts supplied by these markets, and the butter is at once made to suit these requirements. Again, Canada is striving hard to capture the butter and bacon markets of Great Britain. An agricultural commissioner (Prof. J. W. Robertson) of enormous ability and business foresight is engaged by the Dominion Goverment to organize the agricultural resources of the country. One of his special functions is to find out what the markets require, and to advise as to the catering for these. The progress of agriculture in Canada since Mr. Robertson, the agricultnral commissioner, took his commission, is simply marvelous. The success is due mainly to the fact that an able man is in charge of the Industrial and Intelligence Department of the Government, and the sagacious, industrious farmers of the country, having confidence in him, carry out implicitly his suggestions.

The tribute Prof. Carroll pays to the phenomenal ability of Prof. Robertson in developing the production and foreign sale of Canadian dairy products, is just and true.

It is the old, old story of brains and good judgment. When will the farmers learn that intelligence is needed at his end of business just as much as it is at the market end? When will he learn that often because there is no intelligence used at the farm end, the market end fails? When will he learn that if he does not produce first-class milk, the creamery and cheese factory cannot make fine marketable butter and cheese? Where is there a place in the business that good adjusting brains, well informed brains are not needed?

HOW MUCH OVER-RUN IS POSSIBLE?

The ascertainment of the true relation of the amount of butter fat in milk or cream to the amount of standard commercial butter that can be manufactured from the same, is daily becoming more and more important. In the nature of

the case, there cannot be an inflexible standard, partly, because butter itself, as well as milk and cream, is of variable composition, and partly, because methods of creaming and churning are not exact and invariable, and the inevitable losses therefore not uniform.

Conceding then, as we must, that exactness is not possible, it remains to ascertain within what limits variations can be accepted without impeaching integrity of purpose or the exercise of ordinary care and produce.

It must be well known to the readers of HOARD'S DAIRYMAN that an over-run of one-eighth (12½%), with 4% milk, is considered by it sufficient to indicate good average work, and that anything less than this calls for investigation, because it indicates either unnecessary losses in creaming and churning (.2 of 1% of the total milk should be the maximum allowance for the losses) or an unnecessary amount of fat in the butter.

On the other hand, it is demonstrable that an over-run of more than one-sixth (16⅔%), with 4% milk, is at least impracticable, and should cause enough surprise to excite suspicion of error or something worse. In the present state of the art of butter making, the inevitable losses incident to creaming and churning can not be reduced below .15 of 1%, and butter containing less than 82.5% of fat should not be accounted of standard quality. It follows therefore, of necessity, when an over-run exceeding one-sixth is reported, that the tests of fat in the milk have been read too low, or that there is too little fat in the butter.

Entertaining these views, it goes without saying, we were not a little surprised to read in a recent issue of the New York *Produce Review*, an article entitled, "Twenty-five per cent over-run possible" and still more surprised when it was discovered that it was not only vicious in principle, basing, as it does, its argument upon a single sample of butter, but its so-called formula for computing the per cent of over-run was wholly inconsequential.

The formula given is: "Subtract fat from butter and divide gain by the fat, and multiply by 100." Applying this formula to a sample of butter containing 85% fat, the author reaches results, which he calls equations, as follows:

100—85=15; 15÷85x100=17.6% over-run.

Over-run nothing! With a good deal of unnecessary circumlocution, he finds that 15 is simply 17.6% of 85. He does not know how much fat there was in the milk from which this butter was made, or whether there was any over-run at all. For all that appears, or is assumed, to the contrary, there may have been 100 or more pounds of fat in the milk for every 100 pounds of butter produced. And yet he appears to have had an incoherent or inchoate idea that the amount of fat in the milk has some connection with the over-run, for he says of his so-called 17.6% over-run, "When the separator and churn losses are taken into consideration, this represents a normal and good over-run."

Notwithstanding this admission, that 17.6% represents a "normal and good over-run," the writer proceeds to demonstrate, or to attempt to demonstrate, that "It is not impossible to obtain an over-run of 25% in an honest way without any apparent injury to the butter." And to substantiate this claim, he cites the case of a sample of butter, entered in the "Iowa Twelve Month's Contest," which analyzed 79.4% fat, 15.5% moisture, 1.6% curd and 3.5% salt. Applying his formula as before, he gets:

100—79.4=20.6; 20.6÷79.4x100=25.94% over-run. To this he adds the qualifying sentence: "If the pounds of milk were taken as a basis for calculation of fat, the over-run would be about 1.5% less," which is simply confusion worse confounded, as pounds of milk have nothing whatever to do with the amount or per cent of over-run.

An indication of the extent to which this writer has failed to grasp the theory of the over-run question is shown by the fact that his formula would give milk of all degrees of fat content, with all degrees of loss in separating and churning, the same per cent of over-run, as it makes the amount of fat in the butter the sole basis for calculating the over-run. Thus, it is quite possible that two butter makers, starting, we will say, with 10,000 pounds of 4% milk, would produce different amounts of butter carrying the same proportion of fat, as one might run 50 lbs. of fat into the skim milk and butter milk, and the other only 15 lbs. Assuming that this butter contained 79.4% of fat, the yield in one case would be 440.9 lbs. and in the other 484.9 lbs., an over-run by one butter maker of 40.9 lbs. and by the other 84.9 lbs. or 10.25% and 21.25% respectively, whereas the *Produce Review* correspondent would have us believe that all butter containing 79.4% fat shows the invariable over-run of 25.97%

The over-run is the difference between the amount of butter manufactured and the amount of fat in the milk or cream used in making the butter, and not the difference between the butter and the fat in the butter, regardless of the losses that occur in manufacturing. Unless one knows the total amount of fat, or the per cent of fat, it is impossible to ascertain either the amount or the per cent of over-run. Inasmuch as the actual losses in creaming and churning are practically the same with 3% milk as with 6% milk, the per cent of over-run will vary somewhat with the per cent of fat in the milk. Thus, in the Iowa case, if this butter containing only 79.4% fat, was made from 4% milk and the losses in creaming and churning did not exceed .15 of 1%, the over-run was only 21.25%, instead of 25.94%. With 3% milk, the per cent of over-run would have been less; with 5% milk it would have been 22.2%; with 6% milk, 22.83%; and with 30% cream, eliminating the loss in separating, 25.37%.

The proper way to calculate over-run is to deduct the loss in creaming and churning from the test and divide this remainder by the required per cent of fat in the butter; this will give the total butter, and the difference between this amount and the total fat in the milk is the over-run. Divide the total over-run by the total fat in milk and the result is the per cent of over-run.

For example, in 100 pounds of 4% milk, there are 4 pounds of fat. If we estimate the loss in creaming and churning at .15 of 1%, the loss in 100 pounds of milk will be .15 of a pound of fat and there will remain 3.85 pounds of fat available for butter. This sum divided by .825, which is the minimum per cent of fat that should be permitted in butter, gives us the figures 4.66+ as the amount in pounds of butter that can be expected from four pounds of fat in 100 pounds of 4% milk. This is an over-run of .66+ of a pound, or exactly 16⅔% more butter than there was fat in the milk.

Or generally, if a represents the total fat in the milk, b the total loss of fat in creaming and churning, and c the per cent of fat in the resulting butter, the following formula will give the per cent of over-run:

$$\frac{\frac{a-b}{c} - a}{a} = x, \text{ or the per cent of overrun.}$$

We are not unmindful of the fact that butter containing not more than 80% fat will frequently pass as extra when fresh, but it remains to be proven that such butter has enduring quality and is not subject to excessive shrinkage. Possibly some method of manipulation may be discovered whereby the amount of water in butter can be increased to the limit of 16% without impairment of quality, but at the present time 13.5% of water, 1% curd and 3% ash must be considered the limit of safety.

Mr. F. S. Peer's Sale of Jerseys.

The average price received at Mr. Peer's Sale of the Golden Fern Importation, held May 12th, at Hoboken, N. J. was not up to expectations. Various causes are assigned, but none of them appear to be quite satisfactory. The imported herdsman comes in for a good bit of unfavorable criticism, as the animals were not in condition to show off to good advantage.

Although nine years old, Golden Fern's Lad sold for $2250 to Mr. T. S. Cooper, a circumstance that ought to appeal to breeders and dairymen alike to revise their judgments in regard to aged bulls. Golden Fern's Lad was not only well born but he had proven his superior excellence as a dairy sire by numerous sons and daughters of exceptional merit. The next highest price, $1,000, was paid by Dr. C. E. Still for Brookhill Fox, a grandson of Golden Fern's Lad through Flying Fox.

After this there was a big drop in prices, the best cow selling at $475 and others from that down to $160. Then bulls came in again for $150 down to $135, and after these came nineteen animals at from $100 to $130 each. Without going into further particulars we give the following summary.

9 bulls sold for	$4080.	average	$453.33
10 bull calves sold for	$290.	"	$29.00
59 sound cows sold for	$8170.	"	$138.47
1 crippled cow sold for	$10.	"	
4 heifer calves sold for	$200.	"	$50.00

Western Guernsey Breeders' Association.

ED. HOARD'S DAIRYMAN:—The summer meeting of the Association will be held at the Helendale farm of Mr. Fred Rietbrock, Athens, Wis.

It is hoped that all members will endeavor to be present, and all intending to go will please notify Mr. Rietbrock at once, 107 Wisconsin St., Milwaukee.

Mr. H. D. Griswold, of West Salem, is to read a paper on "The Guernsey Grade for the General Farmer."

The other subject for discussion is "Do We Pay too Much Attention to Fancy Points in the Guernsey."

CHARLES L. HILL, Secretary.
Rosendale, Wisconsin.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

Weight of Green Corn Per Acre and of Same Corn, Field Cured.

Will some of your many readers tell me through your paper about how much an acre of green corn ready to cut for the silo, that would make when dry, say, 40 bushels, per acre, would weigh, and what it would weigh if allowed to stand until ripe and cut and shocked up until winter; in other words, what we use to call shock corn in Missouri. I want to find out if I can which is worth the most to feed to a few cows, a crop of corn and a crop of sugar cane, or two crops of sugar cane. I can raise a crop of corn and get off the ground and then sow it in cane and get a good crop, or I can sow it in cane early and get two good crops in a year. We have no silos in this country, and yet I don't know but what they would pay and have enough of them so we could feed it 365 days in the year. D. M.
Taylor, Texas.

We shall be very glad to have the opinion of readers on this subject, but meantime, we feel like saying that a crop of forty bushels of corn per acre is not creditable to the locality where it grows. The fault may be partly due to the soil or to the climate, but, in the majority of instances, it is more likely to be due to lack of proper tillage or rotation of crops. A yield of one hundred bushels per acre is by no means uncommon in the corn belt and an average of less than sixty bushels per acre should be accounted a poor crop almost anywhere. A field of corn yielding sixty bushels per acre would make about four and two-thirds tons of field cured forage, that is, if cut off near the ground and cured in shocks or stooks. In the green stage ready for the silo, its weight would be somewhere from eight to ten tons. Deducting one-third from these figures would give the probable yield of green corn and field cured fodder where the yield of grain would be only forty bushels to the acre.

Southern Missouri as a Dairy and Stock Country.

I think of going to the Ozark region, Southern Missouri, but some say that it is too hot and cows wont do as well as in a northern climate. Grasses grow well, particularly clovers, and also much fruit, and the shorter winters induce me to go there instead of north. Land is too high priced here for a poor man. Should like your opinion of South Missouri as a dairy and stock country. M. E. B.
Crete, Neb.

It would be manifestly improper for us to make our reading columns a vehicle for exploiting the merits of the different sections of the country for dairy purposes or otherwise. It is doubtless true of Southern Missouri, as it is of most other places, that some men succeed where others fail. It seems to us that in so important a matter as changing locality, a person should spy out the land for himself rather than depend upon the advice of friends or strangers. In these days of cheap traveling, it is a comparatively inexpensive matter to go five hundred or a thousand or two thousand miles even.

Churns and Cream Ripeners.

We are about to purchase a new churn, have always used a Disbrow, and am well satisfied with the work it does, but like the mechanical appearance of the Dairy Queen. If it will work as well as it looks, it is a much superior machine. We print our butter right from the churn, therefore it must be properly worked and I am afraid the automatic roll of the Dairy Queen will not perform right. Can you tell me anything about it or where I can find out about it aside from the manufacturers? Also would you consider it wise to invest in a cream ripener rather than cream vats when you have a nice, clean, cool, well ventilated vat and churn room? How can you keep cream cool in the ripener through the night? E. P.
Bloomington, Ill.

"Many men of many minds" have approved churns of various kinds. In the nature of things, it is quite impracticable for us to become familiar enough with all the different styles and kinds of churns to pass judgment upon their respective merits. The manufacturers of dairy machinery, as a rule, are very willing to give references and it is not a very difficult matter to write to the parties to whom reference is made and get their opinions, and in important matters it is even practicable to visit premises where they may be in operation.

The so-called cream ripeners are coming more and more into use in large creameries because of the facility with which the temperature of the cream can be controlled, but where one has a "nice, clean, cool, well-ventilated vat and churn room" it may perhaps be doubted whether the ripener would be very much superior to a good vat.

Twin Calves of Opposite Sex.

Should like to ask if twin calves of opposite sex will pay to raise as breeders? I am told heifer will not be a breeder. What is your opinion?
Crete, Neb. M. E. B.

A heifer twin to a bull is called a Free Martin, and it is very seldom that they prove to be breeders. The bull in such cases is usually of normal capacity.

Forms for Building Concrete Walls.

Can you tell me how to construct a form for building a concrete wall 9 or 10 ft. deep and 14 ft. in diameter, on which to place a tub silo?
Auburn, N. Y. E. J. R.

As stated some weeks ago, we entertain a belief that it would be much easier to go on the ground, fit up forms and build concrete walls, than it is to attempt to describe how it could be done, because in the former case, one would have the advantage of trying various methods when it was discovered that the first attempts were failures. Still more difficult is it to describe how movable forms could be constructed for use in erecting these walls Such forms have been made, and, as we understand, have been patented, but we despair of being able to give any intelligent description for constructing them. If any of our readers can furnish information of this character, they will be confering a great favor on a great number of their brethren.

Sugar Beets for Cows.

Will you kindly tell me if sugar beets—those grown and used by beet sugar factories—are the proper thing to feed to milking cows? W. H. F.
Green Bay, Wis.

Sugar beets undoubtedly make good feed for milking cows but it is doubtful if they can be raised for this purpose with profit. Mangels are much easier grown, much easier harvested and produce much larger crops, although they do not have quite so high a feeding value.

When to Sow Millet.

Will you tell me through your paper how and when to seed millet. I have a piece of ground that is too wet to plant corn, and do not want to put potatoes on it. Can land be seeded down with millet as a nurse crop? How much millet will it take to the acre? A. T.
Nowthen, Minnesota.

Millet may be seeded at any time from early spring until midsummer, as it comes to maturity in from sixty to ninety days. The amount of seed required per acre, varies from one to one and one-half bushels.

Millet is accounted a hard crop on the soil because of its rapid growth and great yield and, hence, we should not consider it a suitable "nurse" crop. And, by the way, what a misnomer this word "nurse" crop is. Instead of being a nurse, it is in fact a robber, and this more particularly if it is permitted to reach maturity.

Early History of the Babcock Test.

[By Dr. S. M. Babcock, Madison, Wis. at the National C. B. Association.]

It is now nearly twenty years since I was first deeply impressed with the injustice arising from the system of pooling milk that was practiced everywhere at that time in creameries and cheese factories. In such factories the milk was paid for, or if the factory was co-operative, dividends were apportioned, according to the amount of milk delivered by the different patrons, no account being taken of the relative values of such milk. I was then employed as chemist at the New York Agricultural Experiment Station, at Geneva, which institution was the owner of four grade Jersey cows. These cows were considerably above average excellence, the four together producing four pounds of butter daily. There was but little difference in the quantity of milk given by the individual cows of this small herd, and they were considered to be about equal value so long as the mixed milk was handled together. But experiments which were planned made it necessary to determine the butter yields of the different animals. This brought out the fact that one of the animals was producing nearly half of the total yield from all four of the cows. Analysis of the milk from each cow showed that the fat contents of the different milks was wholly in accord with the results obtained by the churn. Subsequent studies with milk from different sources entirely confirmed these results, showing conclusively that the butter producing capacity of a cow is measured by the amount of fat contained in her milk. This fact is accepted by nearly every one to-day, and from our present point of view it is difficult to understand how so evident a proposition could ever have been questioned. In those early days, however, the majority of dairymen firmly believed that the butter value of milk or cream could only be determined by the churn. It must be remembered that there was more excuse for skepticism regarding such questions in those days than at the present, for the principles involved in the manufacture of butter were not as well understood, nor were the appliances available as efficient as those now used. It must also be borne in mind that the change proposed was a most radical one, it being from a practical method, long in use, which everyone understood, to a purely theoretical one with which none of the parties involved were accustomed. Everyone believed the churn, and scarcely anyone trusted the chemist, who in many cases did not even know how butter was made. This is well illustrated by the hold which "official" churn tests of individual cows had upon breeders and dairymen all over the country. In such tests the churn was always used and no matter what results were obtained they were usually accepted without question. It was not unusual for enormous quantities of water to be retained in the butter, and in some cases, there is good reason to believe most of the milk solids were also incorporated with it. The sharp competition in this line went so far that some tests were made and accepted which demanded upwards of 25 per cent of fat in the milk if the butter obtained was of an average standard. In one case a pound of butter was obtained from less than three and one-half pounds of milk. In another, over six and one-half pounds of butter was reported in one day from a cow giving a moderate amount of milk, and it seemed that the limit would only be reached when the produce of the cow was pure butter. At that time there was no published analysis of pure milk showing over 9 per cent fat, and this figure was only reached when the yield was very small. In a few cases it had been my fortune to obtain samples of milk from some of these phenomenal cows, which in no case showed abnormal quantities of fat when subjected to analysis.

In view of these facts I had no hesitation in expressing my disbelief in those phenomenal tests which demanded more than 10 per cent of fat in the milk. In consequence of my expressed opinion I was called upon to make analyses of the milk and butter in some of the official tests. In none of these were there phenomenal yields of butter, but, what is of greater importance, there was found in every case substantial agreement between the fat content of the milk and the butter produced. This principle was not universally accepted, however, it being claimed by leading breeders that butter fat was produced in milk after it was drawn, by the methods of handling which they practiced, and in this way abnormal yields were accounted for and often accepted. All sorts of claims were made and persisted in, and years later, after the relative value plan had been quite generally accepted in creameries, the proposal to make the fat content of milk the basis for awards at the Columbian Exposition in Chicago met with so much opposition that it was at one time doubtful if any test could be arranged, and, as it was, only a few of the Breeders' Associations invited, took part.

The result of observation with individual cows turned my attention early to the injustice brought about by the pooling system in factories where very wide differences often occurred in the quality of milk supplied by different parties. The only satisfactory solution to this question which appeared at all feasible was to make the fat content of milk the basis for dividends. But with the analytical methods available at that time the expense was entirely too great, as the necessary determination could only be made by trained chemists with appliances only found in well equipped laboratories. The only rapid method for the estimation of fat in use at that time was that described by Soxhlet, which required considerable skill and was too complicated for general introduction in factories.

The problem of a simple fat test had occupied my mind for several years before I came to this state. I had then great hopes that the lactocrit which was being used to some extent in Europe might answer the purpose, and I intended to give this apparatus a careful test, but found on my arrival at the Wisconsin Experiment Station that Mr. Short, who was then a chemist in that institution, had devised a simple method for estimating fat in milk which seemed better fitted for factory use than did the lactocrit. Short's test was the first that gained sufficient foothold in the factories of this country to be used for determining the relative value of the different patrons' milk. It did much to direct public opinion to the great need of some adequate control in factories, and was followed in a short time by a number of other tests designed to accomplish the same end. All of these tests required considerable skill in manipulation, and consumed more time than the average factory man was willing to give. Besides, none of them could be used in the estimation of fat in the waste products of the dairy, such as skim milk, buttermilk or whey, where the amount was much less than 1 per cent. It was therefore impossible, with any of these tests, to locate and determine losses resulting from careless work and imperfect apparatus; but in spite of these deficiencies Short's test, and those which followed it were of inestimable service to the dairy industry of this country, as they directed attention to the great inequalities which existed in the old system, and

"ADVERTISEMENT".

WHEN WILL YOUR POSTAL COME?

You who are sick and need help—when will you ask me for it?

Why do you wait, while thousands are getting cured? They simply write me a postal—just as I ask of you.

I will mail you an order—good at any drug store—for six bottles Dr. Shoop's Restorative. You may take it a month on trial. If it succeeds, the cost is $5.50. If it fails, I will pay the druggist myself—and your mere word shall decide it.

Don't you realize that such an offer would ruin me, unless I had a remarkable remedy? Could there be better evidence that I am curing the sick ones who write?

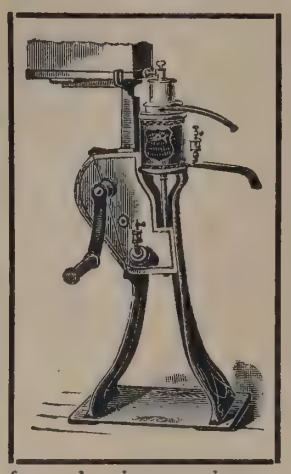
My records show that 39 out of each 40 pay for the treatment gladly, because they get well. There are 39 chances in 40 that you will gladly pay, too.

My success comes from strengthening the inside nerves, which alone operate the vital organs. I have spent my life in learning how to do it. A weak organ means weak nerve power. It is like a weak engine that needs more steam. To doctor the organ is useless; what it needs is power to act. My restorative alone brings back that power, and in most of these diseases no other way can cure.

My book will tell you why.

Simply state which book you want, and address Dr. Shoop, Box 934, Racine, Wis.

Book No. 1 on Dyspepsia.
Book No. 2 on the Heart.
Book No. 3 on the Kidneys.
Book No. 4 for Women.
Book No. 5 for Men (sealed)
Book No. 6 on Rheumatism



Mild cases, not chronic, are often cured by one or two bottles. At all druggists.

Don't Worry

Don't lie awake nights worrying for fear your wife or children will get caught in the gears of your cream separator, but be on the safe side,

BUY A

U. S. SEPARATOR

and sleep well. The U. S. is the kind that has the gears all enclosed in an iron casing, so that it is absolutely impossible for any one to get caught and injured in them. Read the following item clipped from the St. Charles, Minn., Union, of Feb. 19, 1903:

Mrs. Gustave Melcher, of Oak Ridge, had her arm caught in the gearing of a cream separator and torn off last Sunday morning. Dr. Bear was called and amputated the injured member below the elbow.

REMEMBER with the U. S. Separator such accidents are impossible, which is only one of the many advantages derived from having an improved U. S. Cream Separator.

For further information write for illustrated catalogues.

pointed a way in which they could be remedied. It was the great and growing demand for a simpler test having a wider range of application that led to my investigations in this line. These investigations resulted in a number of the tests, some of which promised well but were not entirely satisfactory. One of these early tests gave excellent results with all mixed milks that were tried, and also with the waste products of the dairy, but failed when applied to the milk of a certain cow in the station herd. While it was doubtful if such cases would often occur, it seemed unwise to send out a test which was incapable of giving accurate results in all known cases. It was through modifications made in this test for the purpose of adapting it to this one cow's milk that the methods involved in the present Babcock test were reached. It is a source of great satisfaction to me that the method as first described has never been modified except so far as the mechanical part of the apparatus has been improved.

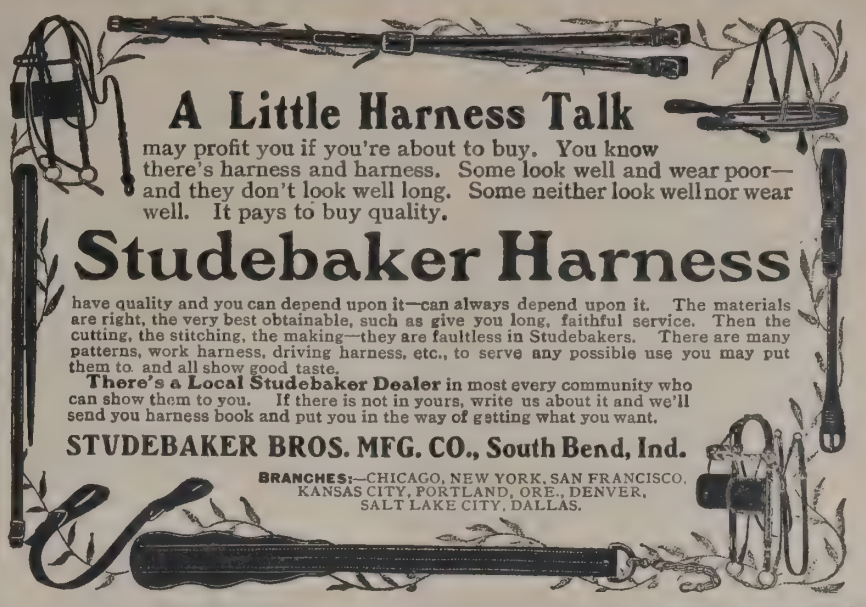
The Babcock test was first described in bulletin 24 of the Wisconsin Agricultural Experiment Station; the bulletin was published in July, 1890. So great was the demand that the edition was soon exhausted, and during the next two years two other bulletins describing the method were issued. From the first it met with unexpected approval and within five years it had been introduced extensively into nearly every dairy section of the world. In this country, in Canada, and in the British colonies of Australia and New Zealand it is now found in almost every creamery where milk from different patrons is received. In some it is used only as a means of control to determine the purity of milk received and for locating losses in the process of manufacture, but in the majority of creameries within these limits it is used for measuring the relative value of the milks delivered and determines the basis upon which payment for milk is made or profits are divided.

In cheese factories it has not been so generally adopted as it has in creameries, for the purpose of determining values. This is natural because the relation between the amount of fat in milk and its producing value is much closer with butter than it is with cheese. Nevertheless, I believe when all factors of the problem are considered that the fat content is as valid a measure of the value of milk for cheese as it is for butter. It is true that rich milks do not yield quite so much cheese for a given amount of fat as do poor milks, but within the limits found in factory milks the difference is not wide and is easily compensated for by the improved quality of cheese from the richer milks.

The test has not been as generally introduced, as a measure of relative values, in the dairy sections of the eastern states as it has in the west and northwest. No doubt the relatively larger number of students from the dairy schools who are operating factories in the west, has been the chief determining factor in this matter. It certainly is not a question of longitude, for on the other side of the world, in far New Zealand, every factory was operated upon this plan before it was generally accepted in Wisconsin. At present it is gaining ground everywhere and I believe in the near future that the relative value plan of fixing values based upon the fat content of milk will be well nigh universal, not only in butter and cheese factories, but in the supply houses which furnish milk for domestic consumption in cities.

No better demonstration of the great need of some adequate means of milk control could be found than that which the rapid and widespread introduction of this test supplied. At the time when this test was given to the public the factory system was greatly demoralized as a result of the practice of pooling milk without any account being taken of its quality. This practice not only offered no inducement to produce good milk, but actually put a premium upon poor milk, in consequence of which the average quality of factory milk was slowly but surely deteriorating. This resulted partly from fraud, and partly from a poorer class of cows upon the farms from which the milk was derived. In every factory association in the country much time and money were expended every year in efforts to prevent fraud through the watering and skimming of milk by patrons, and I believe in the aggregate that the cost of these efforts was as great as is the testing of milk today. The point had been reached when honest producers of high grade milk were fast withdrawing the patronage from factories and going back to private dairying rather than to submit to the injustice involved. The time therefore was most opportune for the introduction of this test which not only relieved the factory operators from unpleasant and unprofitable inspection duties, but also made it possible for all grades of milk to be pooled on an equitable basis.

In spite of the almost universal need of such a test its general introduction was beset with many difficulties. The first of these which I shall mention resulted from the method not being protected by patents. In consequence of this a great variety of very cheap and defective machines were put upon the market. These machines in many cases did very unsatisfactory work and resulted in much dissatisfaction, and for a considerable time reacted against the test. Such apparatus has, however, been driven entirely out of use by the substantial and easy running machines which have been upon the market for a number of years. Another danger arose from the widespread tradition that butter was the only legitimate standard, and that the test should be so modified as to show butter yield instead of per cent of fat. In order ty cater to this condition and thus secure trade, a number of manufacturers sold outfits provided with pipettes, for measuring milk, of larger capacity than the standard of 17 6 cc. As no two persons had the same idea regarding the probable over-run of the churn there was naturally considerable variation in the size of these pipettes. I have known of pipettes delivering 17 cc, 17.5 cc, 18 cc, 20 cc, and 22 cc being sold, all of which were supposed by the users to be correct. In one creamery I myself found three different sized pipettes in use. Is it any wonder that under such conditions variable results should have been obtained and results should have been to discredit it? These defective pipettes were at the time aptly designated "fool pipettes" by Mr. Gurler. Fortunately their use has been almost entirely discontinued and today only the standard 17.6 cc. pippette is sold with the apparatus.



There has been much less trouble with incorrect graduation upon the test bottles, than with high or low readings in favor of either the patron or the factory and whenever this has occurred it has been the result of carelessness on the part of the makers, and not designed to give high or low reading in favor of either the patron or the factory operator. In several states there are, at the present time, laws providing for the examination of pipettes and test bottles as to their accuracy, and the use of defective apparatus is forbidden. These laws are doing much to obtain a high standard of accuracy, and there is now a very small percentage of poor apparatus on the market.

The most serious danger which has operated against the test is that arising from intentional misuse, or from misrepresentation of the results obtained. It often happens that the test is read too high or too low intentionally. Sometimes where milk is bought the test is read low in the interest of the dealer, and sometimes it is read low in order that the overrun may appear large and thus show a high grade of work. Sometimes high readings are made to attract patrons from neighboring creameries. Sometimes, where milk is paid for upon a butter basis, the test is represented as showing actual butter yield, the overrun being all appropriated by the company. Sometimes in cooperative factories, where milk is paid for by the test the poorer milks have been read high and the rich milks low in order to make the real difference appear less than it is. In this manner and others the test has been used in fraudulent ways. Probably the danger of fraud in this direction is no more than that from incorrect scales and false weights. Most cases of this kind could be avoided by a more general practice of testing milk on the farm by the patrons themselves. They will all disappear when the underlying principles of the dairy industry are better understood, and so the future has little to fear from them.

Elgin, Ill., May 25, '03. H. C. B.

A North Carolina Herd Report.

ED. HOARD'S DAIRYMAN:—Enclosed find $1 to renew my subscription to the DAIRYMAN. I do not want to miss a single issue. I am a little late in renewing, but hoped to be able to send you a few subscribers, but I find it a hard job in my section of country. I am almost alone in the dairy business in this county, and no one seems to appreciate the work of the DAIRYMAN. I am very much interested reading the herd reports, so will give you what my herd has done in 1902. I milked an average of 30 cows that made 11,000 lbs. butter, or an average of 366 lbs. to the cow.

I started dairying ten years ago with four registered Jersey cows, have bought several since and also sold a good many. I now have a herd of thirty milkers and thirty-five head of young stock. My success, if it can be called success, is largely due to the DAIRYMAN, which I have read from the time I got my first cows. By the use of scales and Babcock tester I hope to reach 400 lbs. to the cow in 1903. I have one cow which will only have to work thirty days more to make her part, so she will have the balance of the year to help some others out, for I still have some that need help to reach the 400-lb. mark. My herd is headed by Biltmore's Torment 60761. R. L. S.

Newton, N. C.

DON'T PUT OFF

CONCERNING OUR ADVERTISERS.

STUDEBAKER ORDERS.

Two sales recently made by the Chicago House of the Studebaker Bros. Mfg. Co. show which way the wind is setting with big concerns that are satisfied with nothing short of the best to be had in vehicles and harness. The first was to the Yellowstone Park Transportation Co., the concessionaires under the government of the transportation privileges of the Yellowstone National Park, who have some 800 head of horses in service. Some time ago this company ordered from Studebakers a few sets of harness, and having tested and compared them with other makes used by them, quickly followed with an order for fifty sets of four-in-hand harness. The order was placed expressly on the superior quality of the Studebaker goods. The other sale was to the W. C. Walch Co. of Chicago and consisted of sixty United States mail wagons and sixty sets of harness to go into the government mail service and to be made after the approved government designs and specifications. These orders, though not of great magnitude as Studebakers do things, yet indicate in a forcible way the high standing of Studebaker goods.

There is not a progressive, thinking man on the farm but that thoroughly appreciates the great convenience of a telephone system that will connect him with his neighbors, and as well with his marketing town. Just think of the saving of your own time and labor, think of its convenience with your own neighbors, think of stepping to the telephone and in a minute, having a doctor on his way to your home. There is no question but that we can all get along without these things, but why do so. The expense of a rural telephone is nowhere near what most people would think when the community takes hold and pushes it along collectively. The readers of Hoard's Dairyman are the progressive, go-ahead farmers of their community, and those who have not the advantage of a telephone system should take the matter in hand. Send to Stromberg-Carlson Telephone Co., Chicago, Ill. for their catalogue which gives a great deal of information in regard to the erection of telephone systems. If you would like to have a system installed in your community, don't put this off, but get the catalogue and be able to talk with your neighbors and others, intelligently on the question. Don't put this off but drop a card today to this firm, requesting their catalogue and mention HOARD'S DAIRYMAN, and you will receive prompt attention. In a hundred different ways the telephone makes farm life safer, pleasanter and easier. The cost is trifling as compared with the advantages and it is safe to say that any farm family that has had a telephone installed in its home for one year could not be persuaded to have it taken out and go back to the old way of living alone.

NEW FENCE CATALOGUES.

The Cyclone Woven Wire Fence Co., of Holly, Mich., with factories also at Cleveland, Ohio, and Waukegan, Ill., announces the issue of two catalogues this season instead of one as formerly. One book illustrates and describes farm fence exclusively while the other covers the ground of ornamental or lawn fencing. The latter work includes some very moderate priced styles of ornamental fence that is nearly as cheap as the common farm fence, but at the same time much more ornamental than many fabrics that sell at a high price. This low priced ornamental fence is especially designed for front fences on wood posts where an attractive job is desired without an expensive outlay.

These catalogues are free and either or both will be sent to our readers in response to a request addressed to the Cyclone Woven Wire Fence Co., Holly, Mich.

OUR PORTABLE ENGINES have many features peculiar to the OTTO and possessed by no other make. The electric ignition is entirely reliable and the battery which supplies the current is of the liquid tight kind. The water cooling device is patented and but a small quantity of water is needed. Our catalogue tells you of these and all other points of excellence for which we make claim. Engines in stock for immediate delivery.

Cheese—American, new, full cream—Twins, 11½@12c; Young Americas, 12@12½c: Daisies, 12@12½c; Longhorns, 11¼@12c; low grades, 10@11c. Brick, fancy, new, 12@12½c; low grades, 11@12c. Limburger fancy, new, 10½@11c; low grades, 8@9c. Swiss, drum, old, choice, 15½@16c; drum, No. 2, 13@14c; Block, choice, 14@14½c; block, No. 2, 12@13c.

Eggs—Strictly fresh laid, cases returned, 13½c; dirties, 12c; seconds, 11c.

SHEBOYGAN, Wis., May 20—Cheese—The offerings on the Sheboygan Call Board today comprised 1,794 boxes of cheese, all of which sold as follows: 7 boxes Twins at 11¾c, 596 Daisies at 11¾c, 287 at 11½c, 18 cases Young Americas at 12½c, 300 at 12¼c. 38 Longhorns at 11¼c, 514 at 11⅜c. Market active.

SHEBOYGAN FALLS, Wis., May 20—Cheese—Twenty five factories offered 2,145 boxes of cheese on the Call Board today and all except 100 boxes sold as follows: 59 Twins at 11⅜c, 6 at 11¼c, 100 cases Young Americas at 12½c, 478 at 12c, 755 Daisies at 11⅝c, 51 cases Longhorns 11⅜c, 596 at 11¼c. Market active, though prices were ¾c to 2c lower than last week.

PLYMOUTH, May 19—Cheese—Twenty-five factories offered 2,582 boxes of cheese which 27 Longhorns were passed on, the balance selling as follows: 42 Longhorns, 11½c, 106 at 11⅝c; 1,027 Daisies, 11⅝c, 887 at 11⅝c; 68 Twins, 11⅞c, 70 at 12c; 315 Young Americas, 12¼c; 40 at 12⅝c. Market active.

APPLETON, Wis., May 14—Cheese—Sixteen factories offered 560 boxes of Twins and all sold as follows: 90 Twins at 11⅝c; 470 at 11½c.

BRILLION, Wis., May 14.—Cheese—The sales were: 167 Twins 11¼c; 541 Daisies at 12¼c: 20 cases Young Americas at 12c: and 18 cases of Longhorns at 11⅞c,

HORTONVILLE, Wis., May 14—Cheese—The offerings were 281 Twins and 32 double Daisies. Sales 239 Twins at 11¼c: and 32 double Daisies at 12¾c. Market active.

MANITOWOC, Wis., May 20 — Cheese — The sales reported were: 550 Daisies and 350 cases Young Americas, all at 11c.

FOND DU LAC, Wis., May 25—Cheese—Sales of cheese on the Call Board today were: 113 Twins, 10¼c; and 325 Daisies, 11c; Market more quiet.

MUSCODA, Wis., May 25—Cheese—The offerings Saturday on the Muscoda Dairy Board of Trade were 263 boxes of Twin cheese and 61 square prints; 80 boxes Twins sold at 10½c, 98 at 10c, 60 withdrawn; 61 square prints at 10c; market easy.

NEW ORLEANS, La., May 25—Butter—Extras, 22½c; firsts, 21c; ladles, 15c. steady

PHILADELPHIA, Pa., May 25—Butter—Market firm. Solids, 22¼c; nearby prints, 24c; western, 23c.

BOSTON, Mass., May 25— Butter market firm at 25c. Recipts light. Cheese unchanged, Eggs easy at 16@16½, at mark steady.

LIVERPOOL, May 25 — Butter—Good United States steady, 75s.

Cheese—Steady; American finest, white and colored, old, steady, 63s; do new, dull, 59s.

NEWARK, N. J., May 25—Butter—Market steady at 22c.

Eggs—16½@17c.

TOPEKA, Kan., May 22—Butter—Creamery butter, 20¼@22c; dairy, 17@18c.

Cheese—Longhorns, 12¾c; Twins, 12¾c; Daisies, 13c.

CANTON, N. Y., May 23—Offered 124 boxes of large cheese; 1,860 Twins and 985 tubs of butter. Large cheese sold for 10½c; Twins at 11c; butter, 22c.

LITTLE FALLS, May 18—Cheese—Sales, 61 lots, 3,640 boxes small white and colored at 11¼@11½c; Twins, 11½c.

BALTIMORE MARKET.

BALTIMORE, May 23—Butter—The receipts, so far this week, have not shown any perceptible increase over last week's receipts; hence, the offerings are not large and the market is kept well cleaned of all attractive stock. Extra creamery is ruling very firm at prices quoted, and for something extra fine our top values might be exceeded. Firsts are in moderate supply and are meeting prompt sale. There is much complaint about mottled and acidy creamery; this kind will not command a price above that of seconds; see if these objectionable features cannot be remedied. Imitation creamery is in rather light receipt; all choice invoices are in quick demand. Ladles, unless fresh and sweet, are more or less neglected; ship no more. Pack rolls solid Packing stock, when fresh and sweet, meets quick sale. Blocks and prints, when not impregnated with garlic, meet ready sale; garlicy stock is hard to sell. The market today closed firm and fairly active on all offering of desirable quality.

Creamery Separator, extras, 22½@23c; firsts, 21@22c; seconds, 19@20c. June Creamery, extras, —@—; firsts, —@—; seconds, —@— Imitation Creamery, extras, 19@20c; firsts, 17@18c; seconds, 15@16c, Iowa & N. W. Ladle, extras, — firsts, 16c; seconds, 14c. Ohio Store packed, extras,— firsts, 13@14c; seconds, 12c. West Va. Store-packed, extras, —; firsts, 13@14c; seconds, 12c. Creamery blocks (2-lb.) extras, 23@24c; firsts, 21@22c; seconds, 20c. Creamery prints (⅛ lb) extras, 24@25c, firsts, 22@23c; seconds, 20@21c. Md. Va., & Penna. Prints, extras, 22@23c; firsts, 20@21c; seconds, 15@16c. Renovated Butter, extras, 19c; firsts, 17@18c; seconds, 15@16c.

Cheese—There are no old cheese on the market at all; hence, our quotations are for new stock, which is in good demand at firm prices.

N. Y. State—Cheddars, fine, 12@12¼c; choice, 11¼@11½c; fair, 10@11c; Flats, fine, 12@12¼c; choice, 11⅛@11¾c; fair, 10½@11c; Small, fine, 12¼@12½c; choice, 11¾@12c: fair, 11@11¼; Ohio Flats, fine, 11@11¼c; choice, 10@10½c; fair, 9¼@9½c; O. Picnic, fine, 11½@11¾c; choice, 10½@11c; fair, 9½@10c; Swiss Cheese, fine, 15c; choice, 12½@13½c; fair, 10@12c.

Eggs—The receipts, while not heavy, are about equal to the requirements; now, as the warm weather is likely to continue, we advise shippers to use every precaution possible in the selection and shipping of their eggs. We therefore suggest that you discontinue the use of barrels and boxes; use only cases with clean fillers. At the close of today's market the price was 15½c. There is a trifle easier feeling pervading and lower prices are likely at no distant day. NOTICE—All receipts are sold subject to loss off. G. M. LAMB & BRO.

301 Exchange Place.

NEW YORK MARKET

NEW YORK, May 23.—Butter—Receipts for the week, 38,585 packages. Exports for the week, 248 packages.

Demand was good from all quarters, and although receipts were largely in excess of last week, there is very little stock of extra creamery left over unsold, and prices are firm at the close, and all good table butter wanted, We note sales of high score. Extra goods at 22¼@22½c; best firsts at 22c, and off quality creameries at 19@21c.

So little New York State Dairy arriving that it is hardly quotable. There were small sales of strictly fancy tubs at 21@22c, and odds and ends of poor to good tubs at 16@20c.

Ladle butter is in better demand and finds plenty of buyers at our prices. Renovated is poor seller in hot weather, and there is more stock arriving than can be sold, and prices are lower and irregular on all kinds except the extreme top quality. We quote:

Creamery, extra, 22c: medium, 21@21½c; poor, 18@20c Dairy, extra, 21c; medium, 18@20c; poor, 15@17c. Ladle, creamery, extra, 19c: medium, 16@18c; poor, 13@15c. Renovated, extra. 19c; medium, 16@18c: poor, 12 to 15c.

Cheese—Receipts for the week, 29,504 boxes. Exports for the week, 11,505 boxes.

Every one wanted fancy new cheese, and supply was quickly taken at full prices; exporters bought all the large cheese at 11¾@12c, and home trade cleaned up the small sizes at 12@12¼c. Exporters were in the market for skimmed cheese, and all the arrivals at 7@10c, the latter prices being paid for fancy light skims. We quote:

Full cream, extra, 12@12¼c; medium, 11½@11¾c; poor, 9@10c.

Eggs—Receipts for the week, 88,423 cases.

Speculation in storage packed stock has about stopped, this caused a falling off in the demand, and prices were inclined to ease off and favor buyers. Near by fresh stock, however, all taken, and is always quick sale in hot weather. We quote:

New York & Penn., strictly fresh, per doz., 17@18c; Western, strictly fancy, per doz., 16½@17c; All Sections, poor to good, per doz., 14@15c

For Sale—Another Guernsey bull calf from best blood in Wisconsin. Also 3-year-old bull, Befilius, well bred. Address MARCH, 1798, W. 39th St., Los Angeles, Cali. 16-2

For Sale—2-year-old Holstein bull, his dam is by a son of De Kol 2nd, who gave under supervision of Cornell University, N. Y., 536 lbs. milk and 26.56 lbs. butter in 7 days; his sire is by a son of Pauline Paul, the champion butter cow of the world, 18669 lbs. milk and 1153 lbs. butter in 1 year; he also has the blood of Pietertje 2nd, the champion milch cow of the world, 112 lbs. in 1 day, 30318 lbs. in 1 year. Price $ 25. WISCONSIN LIVE STOCK ASSOCIATION, Appleton, Wis.

HEY, THERE! JUNK MAN!

I want to know how much you will give me for one of those separators that claim to be "just as good" as the

DE LAVAL CREAM SEPARATORS

I put in one of them last year because the agent claimed it was "just as good" as a DE LAVAL machine and was $10.- cheaper. I have looked about and gotten some separator experience since then and I find now that I could have bought a DE LAVAL machine of greater actual capacity for less money in the first place, while I have lost money every day through the imperfect skimming of this machine, aside from hard running and trouble of all kinds from infernally poor construction.

I am going to have a DE LAVAL machine now if I have to "junk" this old one for scrap-iron. I know it will save its cost the first year of use and should be good for twenty years. I find all well-informed dairy farmers are using DE LAVAL machines and that there are over 400,000 of them.

A De Laval catalogue may save this experience.

60 Cents from Fort Atkinson, Wis., Modern Woodmen's Picnic at Janesville, Wis.—Via the North-Western Line. Excursion tickets will be sold Thursday, June 4, limited to return the same day. Apply to agents Chicago & North-Western R'y.

WALTER JAUNCEY, manager of the Spottswood Herd of Guernsey cattle, owned by Mr. Edward T. Price of Broad Axe, Pa., has gone to the island of Guernsey for the best that locality affords to be added to the Spottswood herd.

Illinois Herd Records.

The Report of Herd "D".

ED. HOARD'S DAIRYMAN:—The cows in this herd consisted of full blood Jerseys, Grade Jerseys, full blood Holsteins, Grade Holsteins, Natives and Grade Short-Horns. There were sixty cows in the herd when the test began, and forty-seven of them remained through the year. Thirteen of the cows were sold during the time the test was being made, for they were found to be inferior and unprofitable animals. The herd contained a great many very fine dairy cows and they made some very good records. The cows were in a good condition during the whole year and were kept in a scrupulously clean and well ventilated barn which was scrubbed once a day and whitewashed twice a year. The sanitary condition was nearly perfect. The cows were not only well cared for but received well balanced rations during the entire year. The results of this herd readily show the importance for every dairyman to take good care of his cows and to feed them well. Giving some of the rations that the herd received at different times during the year, will show clearly how well these cows were fed.

From Sept. 1st to the middle of October, to the cows giving the largest flows of milk, the rations consisted of six lbs. of grano-gluten and all the green corn they would eat up clean. From October 15th to December 7th, the ration to the best milkers was about as follows:

FOOD	Lbs.	Dry Matter.	Protein.	Carbo-hydrates.	Fat.	Cost.
						Cents
Grano gluten...	5	4.71	1.335	1.940	.610	4.5
Corn meal.....	3	2.67	.237	2.001	.129	3.0
Corn Silage....	45	9.40	.405	5.085	.315	4.5
Timothy hay....	5	4.34	.140	2.170	.070	2.5
Total nutrients		21.12	2.117	11.196	1.124	14.5

The ration fed from December 7th to February 1st was as follows:

FOOD	Lbs.	Dry Matter.	Protein.	Carbo-hydrates.	Fat.	Cost.
						cents
Shorts.....	3	2.65	.366	1.50	.114	2.7
Corn meal.....	2	1.78	.158	1.334	.086	2.0
Gluten meal.....	3	2.64	.963	1 236	.075	4 2
Corn Silage.....	45	9.40	.405	5 085	.315	4.5
Hay.....	5	4.34	.140	2.170	.070	2.5
Total nutrients..		20.81	2.032	11.325	.660	15.9

The cows seem to do better when fed grano-gluten and corn meal than when they were fed shorts, corn meal and gluten meal.

The ration from February 1st to March 15th was 5 lbs. of grano-gluten, 3 lbs. of corn meal and 50 lbs. of silage, and timothy hay. From this time on until the cows were turned out to grass, they received about the following ration:

FOOD STUFFS.	Lbs.	Dry Matter.	Protein.	Carbo-hydrates.	Fat.	Cost.
						cents
Grano-gluten...	7	6.60	1.869	2.716	.868	6.3
Corn meal.....	3	2.67	.237	2.001	.129	3.0
Silage.....	60	12.53	.540	6.780	.420	6.0
Total nutrients		21.80	2.646	11.497	1.417	15.3

It will be noticed that this ration contains no hay, corn silage being the only roughage that the cows received. The cows did very well on this ration, and when they were turned out to the pasture, which was about June 1st, they were in good condition. In June the cows received about 4 lbs. of grano-gluten a day besides a grass pasture. In July and August they received nothing but pasture grass. The above rations apply more to the general feeding of the best milkers in the herd, the strippers and poor milkers getting according to the amount of milk that they were producing.

It should be observed that the rations given to the cows during the year did not contain a large amount of grain, but each one contained a liberal amount of nutrients for cows that were giving large flows of milk and yielding a large amount of butter fat. It will also be noticed that each ration contained over 2 lbs. of protein. This can be accounted for when grano-gluten is compared with bran or oats, for it contains twice as much digestible protein, therefore it is not necessary to feed as many pounds of the grano-gluten as we would have to feed of bran or oats to get the same amount of digestible protein.

The above facts are mentioned so that the reader will not be misled when he compares the total amount of grain consumed by each cow in some other herd. When the cows in this herd were not receiving grano-gluten they were receiving gluten meal which is a by-product of glucose sugar refining companies. This feed is also very rich in protein. It contains about 32 per cent of digestible protein. These facts demonstrate very clearly that it often pays farmers to sell some of their oats or corn and buy some such by-products as gluten meal, gluten feed, grano-gluten, oil meal or dried brewers grains, etc.

No. 129 yielded the most butter fat. She gave 8949 lbs. of milk, 4.52 per cent fat, 404 lbs. of butter fat or 472 lbs. of butter.

No. 324 yielded the least butter fat. She gave 3364 lbs. of milk, 4.06 per cent fat, 136 lbs. of butter fat or 159 lbs. of butter.

The average production for each cow in the herd was 5911 lbs. of milk, 4.45 per cent fat, 263 lbs. of butter fat or 306 lbs. of butter.

Cow No. 147 made butter fat the cheapest. She charged 7.5c to produce one pound of butter fat and 35.5c to produce 100 lbs. of milk.

Cow No. 44 charged the most to make butter fat. She charged 22.4 cents to make one pound of butter fat and $1.03 to make 100 lbs. of milk,

The average cost to produce one pound of butter fat was 12.3 cents and 54.9 to produce 100 lbs. of milk.

Cow No. 47 gave a profit of $57.22 and cow No. 44 charged 18 cents for her board.

The average profit of each cow in the herd was $26 64. While the average profit of each cow in this herd is very good, it would perhaps have been better if the owner could have personally looked after his cows. The cows were entirely cared for by hired help.

TABLES GIVING THE PROFIT OR LOSS OF EACH COW IN HERD "D".

GROUP I. Kept at a Loss.

No. of Cow	Lbs. of milk	Per cent Fat	Lbs. of Fat	Lbs. of Butter	Gross Returns	Cost of Feed	Loss

Elgin, Ill. A. J. GLOVER.

Experience with Cow Peas.

The cow pea is a new crop in this part of West Virginia. It has not been tried by many but a number are going to try it this year. Many get the idea that the cow pea, as it is a soil enrichener, does not need either fertilizer or a good soil in which to grow. While it has the power of drawing upon the unlimited supply of nitrogen of the air, it cannot get the other elements of fertility from that source, but it must look to the soil for potash and phosphoric acid. The cow pea is a heavy feeder upon all of these elements and unless the soil already has a sufficient quantity they must be supplied by artificial means if a good crop is grown.

Then scientists tell us that the bacteria necessary to enable the legumes to gather nitrogen from the air do not flourish in an acid soil, so this difficulty may have to be overcome in some instances by the application of lime. Some soils do not contain these bacteria and unless the soil is inoculated the crop may become a nitrogen consumer instead of a nitrogen gatherer.

If tubercles form upon the roots of the plants the nitrogen gathering properties are all right. Then another difficulty must be overcome and that is, the weeds must be sufficiently set back to give the cow peas a chance to start, at least. This has been the greatest cause of failure so far as I have noticed in this section. The land is not very well prepared to start with and the cow peas were sown broadcast and just let go. It takes the cow peas several weeks to get a start to grow so that they can do anything toward contending with the weeds. By this time the weeds have such a start that the pea crop is seriously damaged if not ruined. The land should be cultivated two or three times before the crop is sown.

I have tried the pea for several years in a small way and have tried several varieties. I find that the Whippoorwill pea is rather of a dwarfish habit for me. This variety is very early. It is earlier than is necessary for this latitude. The Black is not so early and makes more vine, but I have raised a yellow pea that has been grown for table use in this section for a long time that I think is the best one that I have tried. This variety matures in about 90 days and in reasonably good soil makes considerable vine. I am going to try a few of the Wonderful or Unknown this year. They may be too late in ripening but I think that the chances are good for this variety to mature in this section. I find that the cow pea developes tubercles in my soil all right but that the soy bean will not. I have tried soy beans three years. The Early Yellow matures but the Late Yellow variety will just barely mature when the frost stays off until October.

The soy bean seems to grow a very plump bean when it reaches maturity, but I think that the cow pea will prove a more profitable crop for this section. The great trouble is that farmers are liable to get discouraged and abandon the crop before they learn how to properly manage both the growing and harvesting, as cow peas are rather hard to get properly cured.—A. J. LEGG in *National Stockman.*

Wooden Hoops for Silos.

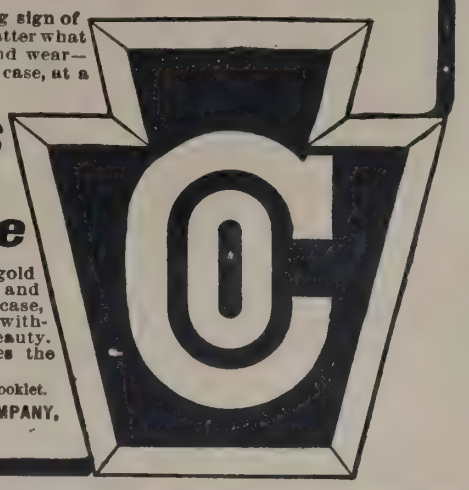
ED. HOARD'S DAIRYMAN:—With regard to wooden hoops for silos, where wooden hoops are used, the lining should be of inch flooring, three inches wide preferred. It should be dry when nailed up, and when complete, tarred thoroughly on the inside; if it is outside and unprotected from the weather, it should be well tarred on the outside also.

The idea is this: the silo must be airtight, and if no way is provided for tightening, as with iron hoops, it must be perfectly dry when built so it will not shrink, then thoroughly tarred to make it perfectly tight, and prevent swelling and shrinking, and preserve from decay. For an out-of-door silo, I would recommend the 2×4 stave, built on the Buff Jersey plan, spiked together edgeways, hooped with iron rods, and all well tarred before put up. I would not use two-inch lumber except with iron rod hoops. Two inch staves do not need to be tongued and grooved, nor beveled.

The reason there are so many silos discarded, as in the neighborhood of Mr. Hill, in Kansas, is no doubt because of improper construction, or improper filling. My first silo was not much of a success, except to show me the value of that (small) portion of the ensilage which kept; but I have kept "everlastingly at it" for about 16 years, and now would not think of dairying or farming without a silo.

Iowa, F. M. PARSONS.

The Sign of a Watch Case



This Keystone is the identifying sign of the best watch case made—no matter what it costs. It stands for worth and wear—for beauty equal to an all-gold case, at a much smaller price. The

JAS. BOSS
Stiffened GOLD
Watch Case

is better protection than a solid gold case, because of its stiffness and strength. Better than any other case, because it will last for 25 years without wearing *thin* or losing its beauty. A reputation of 50 years proves the value of the **Jas. Boss Case.**

Consult the jeweler. Write us for a booklet.

Alfalfa Experiences.

[Press Bulletin.]

During the winter of 1902 a list of between 600 and 700 successful alfalfa raisers in this state was collected, and to each was sent a report blank, calling for a definite statement regarding a number of the processes he employed in obtaining his stand of alfalfa, and also regard his subsequent care of the crop. More than five hundred satisfactory replies were received, representing eighty counties in the state. A study of this large number of reports from successful alfalfa raisers, gives some valuable information respecting alfalfa culture.

There were 288 stands reported upon upland, and 273 upon bottom land. Even in the western portion of the state the amount of alfalfa on the upland is shown to be considerable, and very satisfactory results are evidently obtained, although naturally the yields of hay are smaller than on the bottom lands of that region. In the eastern part of the state somewhat heavier yields appear to be obtained from bottom land, but loss from winter killing or other cause is greater. Twenty-three reports state that upland is more satisfactory than bottom land. These come principally from the eastern portion of the state or the irrigated land of the western portion.

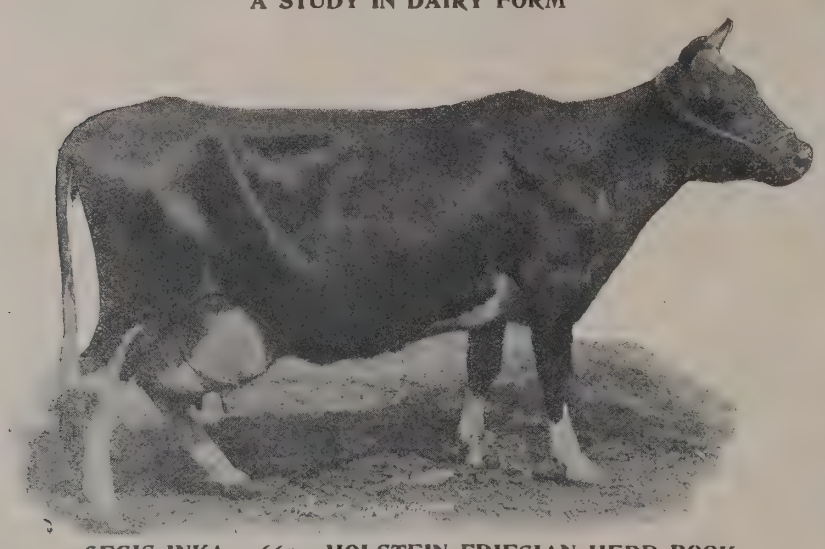
An astonishing feature of the replies is the large amount of alfalfa that they show to be growing on land with a clay subsoil. Sandy clay, clay loam, clay and lime, etc., were not counted as clay. In spite of this limitation, 245 clay or gumbo subsoils are reported. A clay or even a gumbo subsoil does not appear to be a barrier to successful alfalfa culture.

The seed bed was prepared by plowing and further working in 373 cases, and by disking or cultivating in 75. Among the latter is one method that appears to be popular and satisfactory. This consists in thoroughly disking corn land after all trash has been removed from the field. In the western part of the state, there are a number of good stands of alfalfa, obtained by breaking prairie sod, disking it, and harrowing in the seed; also by disking the unbroken sod, and harrowing in the seed. The latter commends itself as an easy way of supplementing the native grasses in pastures. The tendency to dispense with plowing on unirrigated land, increases with the distance westward from Missouri.

A study of the dates of sowing alfalfa seed in spring shows a range from early March to late June, although where advice was volunteered it was practically unanimous in favor of early sowing. There were only eight reports of summer or fall sowing, of which one was sown in July, four in August, and three in September.

In 108 cases a nurse crop was used, while in 393 cases the alfalfa seed was sown without that of any other crop. The use of the nurse crop was largely confined to extreme eastern Nebraska and the irrigated land of the west. Many persons who used a nurse crop say that they would not do so again. It has been recommended to use a light seeding of small grain, sown earlier or with the alfalfa, to prevent damage by severe winds. When sown in this way the nurse crop is mown when eight or ten inches high, to prevent it smothering the alfalfa.

In 55 cases the seed was put in with a drill, and in 447 cases it was sown broadcast. This is at least an indication that if a drill is not available a satisfactory stand can be obtained by broadcasting and harrowing in, provided the other conditions are favorable.



There were 138 reports of less than twenty pounds of seed per acre being used, and 336 reports of twenty pounds or more being sown. The evidence seems to be in favor of the use of at least twenty pounds of seed per acre.

Of persons having practiced disking alfalfa in the spring or at other times, 138 report that beneficial results have been obtained, while seven report that disking has been ineffective or injurious. By disking alfalfa is meant going over it in the spring with a disk harrow before growth starts, or during summer immediately after cutting for hay. It is customary to set the disks at a slight angle. This cuts the crown root and stirs the soil. Some of the correspondents prefer harrowing ing to disking. Where positive objection was made to disking, it was based on the claim that it caused the crowns to become diseased. The great bulk of the evidence was, however, in favor of disking.

Of the persons who have manured alfalfa, either by plowing in the manure immediately before seeding or by spreading it on the field after a stand had been obtained, 110 obtained beneficial results, and 13 found it to be ineffective or injurious. Objections are based on the claim that plowing in manure causes the soil to dry out, but objections to spreading manure on alfalfa are rather indefinite in their nature, except that on low land it makes the growth too rank, and the alfalfa falls down. Many of those who advocate its use, specify that the manure should be rotted and fine. One man suggests harrowing after spreading, to fine it. The reports of beneficial results from plowing under manure comes largely from the eastern portion of the state, but the use of fine manure applied as a top dressing has proven beneficial in all parts.

T. L. LYON.

A STUDY IN DAIRY FORM

SEGIS INKA, 36617, HOLSTEIN-FRIESIAN HERD BOOK

Property of Averill & Gregory, and included in their sale June 4 and 5. In the Holstein annals there are only three cows with larger records, as she is there credited with 28 lbs. butter in seven days.

Let Them Help Themselves.

They'll not take too much, and they'll get it as they want it. Don't force animals to eat salt when they don't require it, by mixing with food.

COMPRESSED

Pure-Salt Bricks

are all salt, no impurities. Improve the quality and yield of milk. A modern convenience, always present, animals never neglected, and costs for each only about a nickle a month. See how they enjoy helping themselves when you place it within reach. For all stock. Buy of dealers or send for free booklet to

A Farmer Who Looks at Dairying Rightly.

ED. HOARD'S DAIRYMAN: — Enclosed find my dollar for renewal of subscription.

Dairying a drudgery? It must be to those that haven't interest enough in it to take a good dairy paper. It is a pleasure to me. My wife says that if I had a stove in the barn she would come out and see me occasionally.

I set some milk scales in the stable last spring, and I found that their accuracy is a great deal better than my judgment of a good or poor cow. The scales tell me that my 50-pound cow was 1,000 pounds behind a 38-pound cow by the last of December. It also interested my hired man; he took increased interest in the well doing of each cow he milked. What interests hired help, is no drawback to the business. WILL GALLUP.

Lime Creek, Mich.

Mr. Gallup's experience in regard to light that a set of scales and a Babcock test will throw on the cow question, is in line with that of all intelligent dairymen. But the value of employing intelligent methods, and their effect on the hired help, in arousing an intelligent interest in them, is certainly very suggestive. It is remarkable and creditable. Of course a hired man will be much more contented in working for a man who can teach him something He will be much better satisfied when he sees intelligent methods carried on. If he isn't it is a sure sign that he has too dull a brain to be around cows.

DON'T PUT OFF

Seeing your friends and having them join in for a good club of subscribers.

Making Soft Early Ripening Cheese.

ED. HOARD'S DAIRYMAN:—Will you please inform me through the columns of the DAIRYMAN how I can make a soft moist cheese, like the N. Y. White Clover cheese? Our cheese are too dry and hard. Will pressing too hard, cause the difficulty? I have a Harris curd mill and our milk is from grade Guernsey cows, without skimming. G. S. W.

Warren, Ill.

ANSWERED BY U. S. BAER, WISCONSIN EXPERIMENT STATION.

I am not unmindful of the necessity for making some distinction between the "export" and "home trade" classes of cheese. I may be permitted to say just here that I have never been quite able to see why we should have these two classes, because we find that our best quality of so called firm or "export" cheese, properly ripened, suits our home trade better than anything else we can give them. I know it is argued that by making a soft, early ripening cheese we can turn our money over quicker. There is a peculiar taste to the New York cheese, that makes it a favorite in some localities. Wisconsin cheese will keep better and longer, and when cured at a low temperature is the prime favorite in the general market and is being shipped into many cities and sold for the New York article.

In the manufacture of soft cheese, the milk should be ripened to that point where ⅛ inch of acid will show on the hot iron within two hours from time of adding the rennet. The temperature of setting the milk should be from 80° to 82°F. The action of rennet at a low temperature is not so rapid, but is of a milder kind and gives a smoother textured curd. After the curd is cut as uniformly as possible and allowed to stand for five minutes, a gentle stirring of the curd may be started. As soon as a goodly amount of whey is formed, the heating of the curd should begin. Combined with steady and gradually increased heating, the mass should be kept in continual motion until a temperature of 96° to 98°F. is attained. The firming of the cheese and formation of the acid is the most critical stage of the cheese making. Immediately on the first indication of acid on moist curd, we remove the whey and spread the curd on racks, not to exceed five inches in depth, to drain.

An excess of acid in soft, moist curd makes cheese crumbly, short, mealy, brittle texture, and often bad flavor with a leaky tendency.

After racking, the curd is cut in strips or blocks and turned frequently.

A heavy blanket to keep the temperature up is preferable to piling the curds. The curd blocks should not be piled at any time over two deep, if one desires to get a fine, smooth, silky texture.

To make a fancy soft cheese, the curd should be milled early and thoroughly mellowed and matured before salting. When curd has assumed a smooth, velvety feeling and the flavor resembles that of ripe rich cream when ready for the churn, it is in prime condition for salt, which should be added at the rate of two to two and one-fourth pounds per thousand pounds of milk.

34 cows and heifers in the McGEOCH HERD have been officially tested with the following results: 10 cows average 20.26 lbs. butter in seven days; average per cent of fat 4.06. 7 four-year-olds average 16.82 lbs. butter in seven days; average per cent of butter fat 3.93. 9 three-year-olds average 15.06 lbs of butter in seven days; average per cent of fat 3.50. 8 two-year-olds average 12.16 lbs of butter in seven days; average per cent of fat 3.60. We have a few young bulls out of some of these cows, and sired by Gem Pietertje Hengerveld Paul DeKol, or Sir Ormsby DeKol for sale. One of these is out of a cow that made official record of 24.88 lbs. of butter in seven days, average per cent of fat 4.47. Are these the kind of Holstein-Friesians you wish? If so, can we not interest you in putting a bull from this class of stock at the head of your herd? McGEOCH HERD is located at Lake Mills, Wis., 56 miles west of Milwaukee. For particulars address H. B. Daggett, Mgr., Station A, Milwaukee, Wis Residence: National Ave. near 40th. Phone, South 1601.

The Rennet, Hot Iron, and Acidemeter Tests in Cheesemaking.

[Paper by Prof. H. H. DEAN, Ontario Agricultural College, Guelph, at Dairymen's Convention in Western Ontario.]

We, in the dairy business, have to work hard, no matter whether it be in the factory, or occupying a public position. That is one of the penalties of being a dairyman, and that is one reason why it is so difficult to get good men to stick to the business. I presume that most men have found this to be the case, and one of the things we are aiming at in our dairy business is to make our work as light as possible, because in any case it is heavy and hard work.

Every improvement which has been made in dairy business has been the result of the application of science or truth to dairying.

We have been for some time groping in the dark after the truth, which nature has hidden from us, and which we only can learn by active research. Every speaker has aimed to give you the result of his search after truth, and after knowledge. The man who merely guesses at things, and tries to give you the impression that it is the result of his research, is a man who is not giving you sound doctrine in dairying. Let me point you to two or three illustrations on this point. What was the dairy cow in her original and natural condition? Do you find any of nature's cows which will give us ten, twenty or thirty thousand pounds of milk? Not by any means. How have these cows been obtained? By the application of scientific principles to breeding and feeding and handling dairy stock. At one time it cost a dairyman a great deal to produce a pound of milk, a pound of butter or a pound of cheese. The application of science to the feeding of dairy cows has reduced that cost materially, and I believe the time will come when we shall understand what is required by the dairy cow, and the present cost of feed will be cut in two. What is there in lucerne that enables the dairymen to reduce the cost of butter or cheese? It is a principle well known to chemists. It is something which acts on the secretive powers of the dairy cow. The nitrogenous compounds in the alfalfa, which the cow digests, enable her to produce milk in the very cheapest form possible.

It was thought at one time, and it is considered by some yet, that the only way to get cream out of milk is to set it in pans or cans; but by the application of a well-known physical law, we got the separator, and we can separate the cream from the milk and get it almost instantaneously, and I do not suppose there is any machine which has done more to help our butter makers than the cream separator.

At one time we were groping in the dark in order to find out how we could test the percentage of fat in the milk. We had lactometers and lactoscopes and pioscopes; and I remember when Prof. Robertson, my esteemed teacher, was lecturing to us students, he illustrated the pioscope, lactoscope, and all the instruments which at that time were known for testing milk. Yet all these were mere guesses. I had last week the pleasure of meeting Dr. S. M. Babcock, a man of scientific research, who has discovered a test by which anyone can ascertain correctly the percentage of fat in milk. Was that the result of an accident? Was that the result of anything less than the application of scientific truth to the principles underlying the separation of fat from milk? No. I might go on and give you innumerable examples of where science and truth have helped the dairymen.

I come now more particularly to the topic which I should have taken last evening, viz, The Rennet, Hot Iron, and Acidemeter Tests in Cheese-making.

We find men today who determine the acidity or sourness of milk by smell and taste, and some men have their sense of taste and smell so trained that they can tell you almost to a nicety what acid there is in the milk, whether it is ready for the rennet or not. They have, after a great many years, been able to train their senses to such a point that they are able to make good cheese without the aid of the rennet test; but men who had investigated this point said, "We must have something more accurate than that," and from them we get the Rennet Test. I want to point out, however, that the rennet test measures the susceptibility of milk to the action of rennet, and does not necessarily measure the acidity of milk. After looking into this matter carefully I have come to the conclusion that there is not any constant relation between the rennet test and the acid in milk; and to the conclusion that the rennet test measures the susceptibility of milk to rennet, and does not measure its acidity. The most important thing for the cheesemaker to know is how to develop and control and keep in check the acid or sourness of his curd. We have been using during the past two summers an acidemeter, and in this connection I would like to say I consider the term "acidemeter" more correct than the "alakaline test." Most of our men have got into the way of calling this the "alkaline test," which is scarcely correct. The term "alkaline test" means a test for alkalinity of any substance, and in this work we are not testing for alkalinity, but for acidity; therefore the words "alkaline test" are incorrectly used, the more correct term being 'acidemeter," or "acid test." I think it is important, if cheesemaking is a science, as we believe it is, that we use correct terms, and that we understand them when speaking about the different steps in the process of cheesemaking.

The Hot Iron Test. Now I suppose I may look out for trouble. Some of you old cheesemakers have used the the hot iron test for so long that you consider it an essential and necessary part of cheesemaking. So far as I have been able to look into the question of the origin of the hot iron test, I find that it is based on an accident, and it is a test that has continued to be an accidental test ever since. A man accidentally found that sour curd would stick to a hot iron. A cheesemaker may determine the acidity of his curd as indicated by the hot iron test, if he uses good judgment, but more depends on good judgment than upon the hot iron test. The hot iron test is not based on truth; it is not based on science. Nobody has yet offered a satisfactory explanation of it. As I said, it is the result of an accident. A man accidently touched some curd against a hot iron and found it to "string"; and from that accident we have the hot iron test as used today. It is in the same class as using the finger for a thermometer, and putting a hot horseshoe into cream to make the butter come, and other things which are based upon witchery, and upon nothing. I am satisfied that in the very near future there will be both rennet tests and hot iron tests "to burn" in the cheese factories of Canada.

So I think in connection with the rennet tests, and the hot iron tests of the cheese factories, in the very near future you will have them to burn. Why? Because the acidemeter is based on well-known chemical laws which chemists understand. A certain weight of alkali

"ADVERTISEMENT."

MEAL TIME CONSCIENCE.

What Do the Children Drink?

There are times when mother or father feeds the youngsters something that they know children should not have. Perhaps it is some rich dessert but more often it is tea or coffee. Some compromise by putting in so much hot water that there is not much tea or coffee left, but even that little is pretty certain to do harm. It leads to bigger doses. Then come the coffee ills.

It is better to have some delicious, hot, food drink that you can take yourself and feed to your children conscious that it will help and strengthen and never hurt them. A lady of Oneida, N. Y., says: "I used coffee many years in spite of the conviction that it injured my nervous system and produced my nervous headaches. While visiting a friend I was served with Postum but it was not well made, still I determined to get a package and try it myself and after following directions carefully the result was all that could be desired; a delicious, finely, flavored, richly colored beverage. Since I quit coffee Postum has worked wonders for me.

"My husband who always suffered from kidney trouble when drinking coffee quit the coffee and took up Postum with me and since drinking Postum he has felt stronger and better with no indication of kidney trouble.

"You may be sure I find it a great comfort to have a warm drink at meals that I can give my children with a clear conscience that it will help them and not hurt them as coffee or tea would." Name furnished by Postum Co., Battle Creek, Mich.

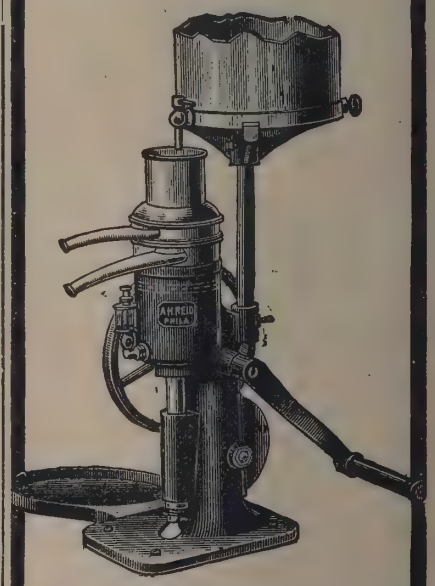
WORLD CREAM SEPARATOR CO. 41 Main St., Council Bluffs, Ia.

THE BOSS
CREAM RAISER

Does not mix water with the milk. Raises all the cream in from 3 to 6 hours, leaving the skim milk pure and sweet, and undiluted for house use and to feed to pigs and calves. It takes care of the cream and keeps it in proper condition to make the best butter at all times. Sweet milk can be drawn off at any time without disturbing the cream. Guaranteed to give entire satisfaction. Write at once for circulars and special introductory prices to Bluffton Cream Separator Co., Bluffton, O.



Shepherd's Aerator

is most simple, most effective, least trouble. While you go on milking millions of air globules from the charged tank are passing up through the milk, driving out all animal heat and foreign odors. Works in shipping can. No other vessel to clean. **King among Aerators.** All dairymen prize it. Write for descriptive circular.

F. P. SHEPHERD & CO., Elgin, Ill.

Reid's Hand SEPARATOR

The "best" separator is that one which does its work most thoroughly and easily, that is built of strongest material, and that is most easily washed and kept in order.

First cost is a great point with a buyer, but ease of running, perfection of skimming and simplicity in washing are even greater considerations.

The **Reid Hand Separator** has but a single cylinder inside the bowl, and skims as closely as one-hundredth of one per cent. Indeed, some tests indicate "not a trace" of fat in the skim milk.

The Reid is perfectly planned and strongly built, and it literally "runs like a watch."

As to our guarantee of excellence, we make the strongest statement that can be expressed in words: **Money back (less freight) if the buyer is not satisfied.**

There is a new (free) booklet about the Reid Hand Separator.

Sizes run from 150 lbs. to 500 lbs. per hour.

A. H. REID
CREAMERY AND DAIRY SUPPLY CO.,

RUPTURE CURED while you work. You pay $4 when cured No cure, no pay ALEX. SPIERS, Box 846, Westbrook Me.

will neutralize a certain weight of acid. The principle is based on science and truth, and if I know anything about the advance in the cheese business, we can only advance as we base our work on science and truth, and, as we depend upon guesswork or any tests which do not give us exact and scientific results, we are to that extent being misled.

We have heard a great deal about the washing of curds. To give you an illustration of how important it is to know what we are doing, I am in a position to tell you that we have found, as a result of our experiments with washing curds, that it tends to materially reduce the acid in the curd. Can you tell me a more nonsensical thing than for a cheesemaker to make the conditions favorable for acid up to a certain time, and then wash the acid out? Can you show me where there is any science in that? It is sometimes advisable to wash curds, such as acidy or tainted curds. A man who does not study these things from a scientific standpoint, is a man who is groping in the dark, and who will not attain that height we are expected to attain in cheesemaking.

What are the advantages of the acidemeter over the rennet test? First, cheesemaking will be based on acid from the beginning of the process. Second, it takes less time to make tests with the acidemeter than with the rennet test. Third, there is less waste of milk and curd. Fourth, there is less liability to error with the acidemeter as compared with the rennet test, because you have not so many things to guard against, such as temperature, strength of rennet, time, etc.

What are the advantages over the hot iron test? It gives the acidity in exact terms. There is less danger of developing too much acid on the curd. Why? Because the acidemeter will tell the cheesemaker exactly how much acid he has, whereas with the hot iron he is guessing at it. Mr. Bell, this morning, pointed out very forcibly the necessity for uniformity in our cheese, and I think the acidemeter will help us to get uniformity better than any thing else we have yet discovered.

I do not advise cheesemakers to throw away their hot iron and rennet tests all at once. You will need to study the acidemeter, and how to get the best results with it, before you use it altogether. On the other hand, do not be so pig-headed that you will not make any change, because the using of it will help you to make better cheese, and will make you a more scientific man. Some men remind me of

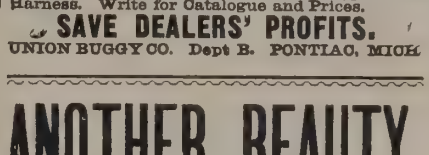
"The poor benighted Hindoo,
He does the best he kin do,
He sticks to his caste from first to last,
And for pants he makes his skin do."

There are some who will stick to anything from first to last, and will make no change. They refuse to see where they can make improvement. In this connection I am reminded of a piece of statuary I saw last week.

My friend, Mr. Millar, and I went into the art gallery, at Milwaukee. As you go in, there is a centerpiece of statuary, a beautiful woman, with her form perfectly poised, a perfect form in every way. Beside her stands a child. The woman is holding a mirror and gazing into it. I fancy the sculptor is making her say: "If there is anything defective in this form I will remedy it—I will make it appear so beautiful that it will charm man so that I will be able to lead him anywhere I like." She was perfect in every way, and yet she is gazing into that mirror, and you could see on her face the expression, "If there is any improvement, I am going to make it, if at all possible." What about the child? It stands with its arms across its eyes refusing to look at itself in the mirror—refusing to see the imperfections of its form; and there are men to-day who are like that child, blinding their eyes with their arms, and refusing to see anything that is wrong, whereas they ought to be like that beautiful woman who, looking at herself, says: "If there is any room for improvement, I am willing to make it."

The Breed and the Man.

ED. HOARD'S DAIRYMAN:—Every little while I notice something crop up about which is the best dairy breed and then it mostly drifts to the ones that were in the dairy test at Buffalo, and the lovers of each breed figure their own to come out best. My idea is, to be honest with each breed, the herd that had the most profit on butter and total solids over the cost of feed was the best.



But those same herds with the same feeders changed round would have shown different results, so I say it's the man, not the cow, so there is no need for the lovers of the dairy breeds fighting about which is the best. They are all best in their own place, and there is a place for them all. It is not the best breed of cattle they want to get at, it is the best breed of herdsmen. T. B.

Your Dairy

May be kept ever so clean, your cattle may be pedigree stock and you may feed them in the most approved manner, but your patrons will never suspect these things if you deliver milk from a ramshackle wagon. An attractive milk wagon attracts trade; it's not a luxury, but a practical necessity.

The Koenig & Luhrs wagons are built for the business. They embody every convenience, are handsome in finish and general appearance, are made of good materials and are so well put together that they'll last for years. A quarter of a century's practical experience has taught us the "know how" of good wagon building. Are you considering a new wagon? It will pay you to get our catalog and prices before placing your order.

VETERINARY.

Queries in this department answered by DR. A. H. HARTWIG, Watertown, Wis.

Swollen Sheath.

I have a boar about 7 months old with a swelling at the end of his sheath. It does not prevent him from serving a sow. L. D. B.
Grimsby, Ont.

ANSWER.

These swellings are often reduced by washing the parts clean with Castile soap and warm rain water once daily; when dry rub with clean lard. The cause is uncleanliness, which irritates the parts.

Texas Fever.

I see by the last issue of tha DAIRYMAN that Gov. Hoard sold a Guernsey to Wright & Son, of Texas. Can you tell me if there is any risk in taking stock from this state to the south, from Texas fever? What precautions, if any, should be taken to prevent trouble and loss? W. F. R.
Peshtigo, Wis.

ANSWER

The best preventive is to keep your stock in good sanitary surroundings, and away from diseased cattle Thorough disinfection is always advisable, which is very inexpensive, and productive of much good in these cases.

Lameness in Hip Joint.

I have a cow that is lame in the hip joint. The local veterinary advised the blister, but she has grown worse. The sore caused by the blister healed very slowly and after it healed, the skin looks red. J. W. T.
Hadly, Mich,

ANSWER.

It is impossible for us to determine the nature of your cow's lameness from the above description.

An Unthrifty Cow.

Have grade Jersey cow that freshened April 1st. She has milked well until two weeks ago, when bull took advantage and forced her, since then she has run down in condition, milks very little now and has a cough.

Have another cow, was unwell for 8 weeks. She will vomit about once a week; first calf; apparently healthly otherwise. C. A.
Dodgeville, Wis.

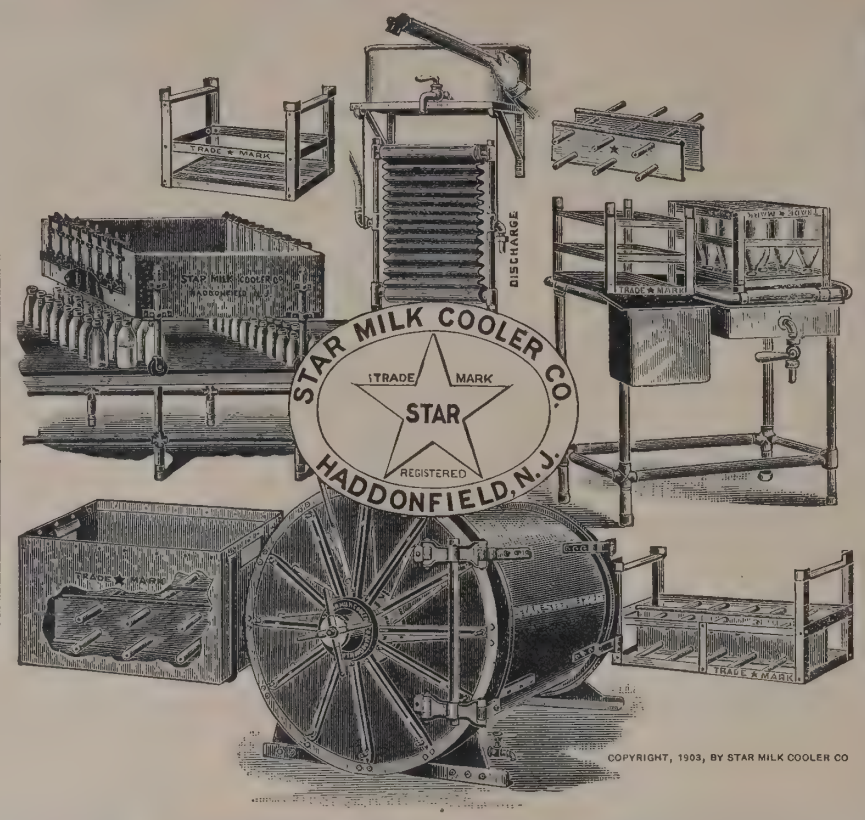
ANSWER.

1. Good nourishment will remedy this case quicker than anything else; the physic will do little or no good.
2. See Emeses, last issue.

Failure to Breed.

I have a cow that dropped her third calf in February last. Came in heat on the ninth day of March and was bred; came in heat again on the first day of April, but was not bred, again came in heat on the twenty fourth of April and was bred, and has not yet gone out of heat. The morning after she was bred the last time, there were drops of blood around the vagina and on the lower side of the rectum. J. W. W.
Stockton, Cal.

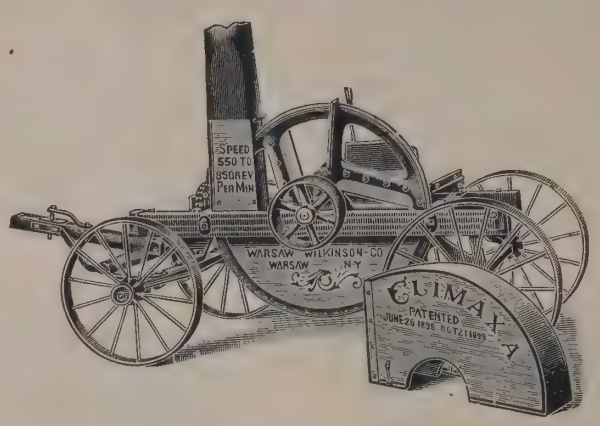
ANSWER.



It is possible that the cow has conceived from the last breeding, but still keeps up the heat which is very often the case. Give her another chance, and if not succcessful, have her examined for an abnormal condition of the genitals, by a qualified veterinarian.

Is it Injurious?

Is it injurious for hogs to have all the water they want to lie in? I have water in the ditch all the time which they have free access to. Also is it injurious with sows with pigs. E. G. S
Ceres, Calif.



ANSWER.

It is not injurious to the health of hogs

STAR SANITARY DAIRY APPARATUS.

CLIMAX
Ensilage and Feed Cutters.

SOMETHING DIFFERENT. CLIMAX machines are not like others. Old ideas have been discarded, and the features are exclusive and original. Some of them are

STRAIGHT KNIVES. Easy to keep in order. Cheap to replace. Cut the material more evenly and do more of it.

ELEVATING. This is done with the same wheel as the cutting. Requires less power and NEVER clogs.

SMOOTH REVERSING GEAR. With this gear there are no cog wheels to break. The machine can be stopped or reversed in an instant without danger of breakage.

SIMPLICITY. No Feed Cutter made has so few wearing parts.

IT IS MOUNTED. Being specially built on trucks, it is just the right height for feeding No platform is required.

All these features are the result of long experience. They mean easier and quicker work and better results. Send for catalogue today.

THE COMPLETE MACHINE.

WARSAW-WILKINSON CO., WARSAW, N. Y.

By the use of Fly Bouncer during hot weather, at a cost of one-half cent per day each, horses will do one-third more work; cows will give one-third more milk on two-thirds the amount of feed required without it. Sprague's Lice and Insect Killer kills lice and mites on poultry, hogs, horses and cattle. Write for free circulars and prices.

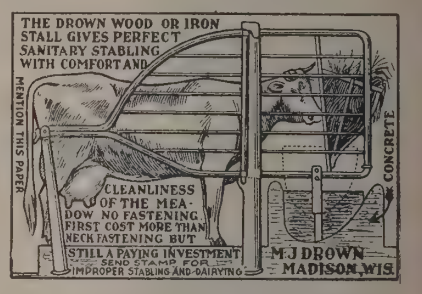
"COME in the evening or come in the morning. when you're looked for or come without warning"—

You'll always find your Tread Power ready for business. OF WHAT OTHER FARM MOTOR—Wind Steam or Gasoline—can this be said? A PERFECT GOVERNOR ensures absolutely even speed. Send for free catalogue.

St. Albans Foundry & Implement Co., St. Albans, Vt.



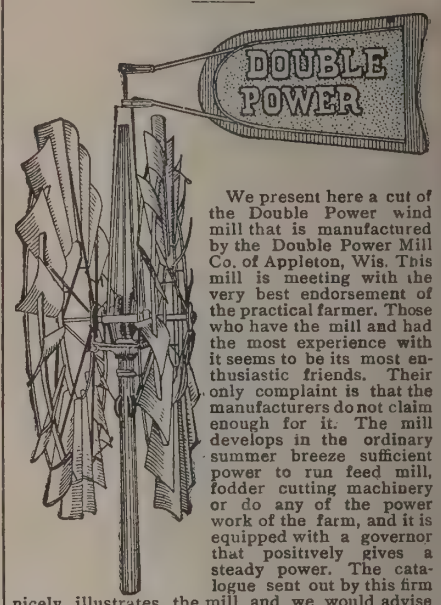


ILLUSTRATION.

We present here a cut of the Double Power wind mill that is manufactured by the Double Power Mill Co. of Appleton, Wis. This mill is meeting with the very best endorsement of the practical farmer. Those who have the mill and had the most experience with it seems to be its most enthusiastic friends. Their only complaint is that the manufacturers do not claim enough for it. The mill develops in the ordinary summer breeze sufficient power to run feed mill, fodder cutting machinery or do any of the power work of the farm, and it is equipped with a governor that positively gives a steady power. The catalogue sent out by this firm nicely illustrates the mill and we would advise every reader of HOARD'S DAIRYMAN to send for one. In illustrating the mill in these columns, of course we shall say nothing that the facts do not bear out, and the least we can say would be to report the opinions of practical farmers who have had the actual experience with the mill. The following letter received from one user:

Stockbridge, Wis., June 17, 1901. Double Power Mill Co, Appleton, Wis., Gentlemen:—The mill you placed on my barn in 1896 is about as good as new. I have seen nearly every geared mill in the country, but none can do half the work of your Double Power. I think each wheel by itself does more work than any other mill because the governor keeps the wheels right for the wind to catch the fans. I think the rear wheel has got as much power as the front wheel. I have ground over 5,000 bags of all kinds of grain with the Appleton No. 3 Grinder, and sawed 300 cords of wood for myself and neighbors. Your mill is so strong I have not had to pay out more than 80 cents for repairs, and would not paid anything if I had oiled it right. As long as I stay on the farm I would rather pay $500 for your mill than take another kind for nothing. Send your customers here, I can tell them better than I can write I have seen your new mills, they are much better than mine. Yours truly, W. J. PILLING.

Another says:

Hayton, Calumet Co., Wis., June 8, 1901. Double Power Mill Co., Appleton, Wis. Gentlemen:—Yours of June 5 at hand I have had experience with several geared mills and would not exchange my Double Power for any I ever saw. I use a 30 inch saw, and with good wind can cut all the wood we can get to the machine. For feed grinding I use a 7 inch burr, but wish it was an 8. With strong wind could run a 9 inch burr full feed. I think with a good fair wind I can do more work than with eight horses on a horse power. The governor makes it run as steady as a steam engine. I bought the first husker you made and with it have husked three hundred bushels in one day. Your mill is the strongest I ever saw. I have not paid one cent for repairs in the five years I have used it. Yours truly, JOHN W. HORST.

to lie in water at their own liberty as they go there to seek comfort.

Bloating.

Some of my cows are bloating. The pasture is blue grass with an abundance of white clover. I have lost one cow by that disease. J. L. J.
Fisherville, Ky.

ANSWER.

The trocar and cannula should not be spared in this trouble, as it gives immediate relief. Two and one-half ounces of hyposulphite of soda and one ounce of ginger may be disolved in a quart of warm water and given at one dose after tapping.

Off Flavored Milk.

I have three cows that get sick about two weeks after they drop their calves. The milk tastes and smells feverish. A neighbor advised me to give the following:

Three oz. salt petre, 2 oz. June berries, 1 lb. Epsom salts, 1 lb. linseed flour.

Divide into 6 doses and give morning and night soon after dropping the calf. They do not seem to do very well after it. E. C. J.
Stanley, Wis.

ANSWER.

Your neighbor's remedy is all right and is worth trying.

Faulty Secretion.

I have a cow recently calved that had one quarter swollen and quite hard. I applied some ointment and rubbed it thoroughly and after about the third day was very soft, but she gives very little milk from the quarter, about 5 or 6 squirts.

I also have a heifer that had a bunch on hind leg at knee joint on outside about the size of a saucer. Last summer it broke and run a little; did not lame her nor was it very sore. Now she also has a number of small ones on inside of leg running up to the bag. E. B. T.
Monroe, Wis.

ANSWER.

The best you can do with both the cows is to keep on milking and apply hand rubbing to the quarter as often as possible. They usually come right with next freshening.

The bunches appear to be warts. Have them removed surgically. This will not affect the milk.

Wart on Teat.

I have a cow that has a wart on one teat. Can this wart be removed while she is milking, without making it so sore that she will be worse than now If so, how?

I have a fresh cow that has such small holes in her teats that milking is very difficult. Can this be remedied, and how?

Is it safe to pasture cows on green oats?

What is good for cows with scours?
Knoxville, Tenn. AMATEUR.

ANSWER.

The wart can be removed with a pair of scissors and the parts touched with a stick of lunar-caustic to prevent bleeding, but it may be advisable to wait until the cow is gone dry.

Open the teat with a bistoury, which can be adjusted so as to make the hole as large or as small as you please.

Green oats will do no harm if you give other food in connection.

You must first of all ascertain the cause and remove same. This must be looked for in the feed they are getting; therefore, make a change in the diet and nature will do the rest.

The Progeny of a Jack.

Will not a Jenny breed regularly if bred to a Jack and will not progeny be either a Jack or a Jenny, as the case may be and also is not always the dam of a Jack, a Jenny? That is, I hold that the dam always of a stud Jack is a Jenny and not a mare and wish your ruling on same as I always consider the DAIRYMAN authority. W. E. S.
Los Angeles, Calif.

ANSWER

The progeny of a Jack and a Jenny would be an ass of either sex, while if a Jack were bred to a mare, the progeny would be a mule.

Pin Worms.

My horse has pin worms M. V. B. G.
Waterville, Me.

ANSWER.

Santonin, 20 grains, aloes, 1 ounce; oil of turpentine, 1 ounce; raw linseed oil enough to make a quart. Mix and drench at one dose.

Cough.

I have a heifer calf nearly 6 months old, that has a dry hacking cough. She will cough three or four times and stop and then in a few minutes will cough again, and so on. SUBSCRIBER.
Kinder Lou, Ga.

When the cough has become chronic a tablespoonful of Fowler's solution of arsenic three times daily, is beneficial. An occasional spoonful of honey on the tongue after meals, will also give good results, in connection with the above.

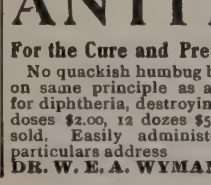
Infectious Abortion.

I have had three cases of abortion in my herd. Two of these are heifers that never gave milk, coming two this spring; the other is a cow coming three this spring, that has been milked the last season. Each of these animals were in heat several times last summer, and along about October they got with calf. WM. H.
McDonough, N. Y.

ANSWER.

Your cows had infectious abortion which may appear again next season, although it is not certain. See page 66-67 of the DAIRYMAN for treatment.

The Abortion Question.



When a cow has once been afflicted with contagious abortion and recovers from it, is she thereafter immune from the disease?

I recently bought about 20 cows from a herd that had passed through a siege of contagious abortion, and out of this number three of the younger members aborted, one in December, one in February and one May 8th. If the older cows have been rendered immune by their experience, I will administer the carbolic acid treatment to the younger cows only, otherwise will doctor the whole herd. The cow that aborted May 8th has been receiving six teaspoonfuls daily, about ¾ oz., of carbolic acid, in two doses. I presume this is heroic treatment, as ½ oz. is the largest daily allowance of acid I have ever heard of being given. This cow failed to pass the placenta, and I understood that carbolic acid is helpful in this trouble. The afterbirth came away in about 70 hours after abortion, and appearances up to date seem to indicate that it is a clean job. The foetus was about 5½ months along. The cow seems to be doing well and shows no signs of harm from the acid, which, though not crystalline, was bought in original five-lb. can, and is supposed to be 95 per cent.
Antigo, Wis. R. E.

ANSWER.

When infectious abortion goes through a herd and is allowed to run its natural course, it does not appear to render the animals immune from the disease. Either the animals are reinfected, or abortion takes place because of a debilitated condition of the generative organs from the first attack. Experience teaches us that carbolic acid has no effect in this disease whatever when given per mouth. See Infectious Abortion, page 66-67 of the DAIRYMAN.

SAVE-THE-HORSE
— TRADE MARK —
SPAVIN CURE.

Positively and Permanently Cures Bone or Bog Spavin, Ringbone (except low ringbone) Curb Thoroughpin, Splint, Capped Hock, Shoe Boil, Wind Puff, Weak or Strained Tendons and Lameness.

From Owner of "Sable Great" (2) 2:22¼:
Riegelsville, Pa., May 18, 1903.
I used "Save-the-Horse" on a very valuable filly that was turned out last spring, and while running slipped and sprung a spavin. At the suggestion of my veterinarian I blistered her twice without any improvement. I then procured "Save-the-Horse" and am able to report an entire cure. The filly goes without the slightest lameness, not even a hitch or a drag being apparent. I believe your great remedy is so valuable that no stable should be without it. LEE S. CLYMER, Prop.,
Durham Knitting Mills, also of Sunnyside Dairy and Monroe Stock Farms and owner of "Sable Great" (2) 2:22¼.

FROM A VETERINARY SURGEON.
(Received by registered mail.)
North Chicago, Ill., May 11, 1903.
Enclosed find $5.00 for one more bottle of "Save-the-Horse. With four bottles of "Save-the-Horse" I have cured three ringbones and two spavins. I bought a colt the other day with two soft curbs which I hope to remove with this bottle.
WM. C. ANDERSON, V. S.
Office Goss House, No. Chicago, Lake Co., Ill.
Memphis, Tenn.
Please send us at once 6 bottles of "Save-the-Horse" for Mr. Ben White of the Village Farm Stables, who recommends it very highly.
W. S. BRUCE & CO., Horse Goods Supply House.
Waterbury Conn., May 17, 1903.
I have used your "Save-the-Horse" and recommend it and you may send me six bottles C. O. D. I can refer you to Mr. Joslin of Joslin & Allen, and A. F. Hinchey, both of Waterbury, friends of mine who have used it and who will give you testimonials. I would like to take the agency for this section. Please let me hear from you.
H. B. LOUCKS, Boarding, Sale and Livery Stable.
Cuba, N. Y.
I had a big four-year-old horse that had a bone spavin. I tried several remedies without success. I used one bottle of "Save-the-Horse" and worked the horse right along. He is cured of the lameness and has been for some time.
Very truly, E. BROWN.
Horse can be worked continuously. Cures without scars, blemish, or loss of hair.
It can be applied at any time, anywhere, any place, and in all conditions and extremes of weather. And no matter what the age, condition or development of the case or previous failures in treating, the concentrated penetrating, absorbing power of this remedy is unfailing.
$5.00 PER BOTTLE.
Written guarantee with every bottle constructed solely to satisfy and protect you fully. Need of second bottle is almost improbable, except in rarest of cases Copy of guarantee sent upon application
If you have a case different from those described in our Booklet or Advertising we will advise you frankly as to the possibility of the remedy effecting a cure. Give explicit particulars, give the veterinary's diagnosis, if he is competent—inform us fully as to the age, development, location of swellings, lameness, action and previous treatment. $5.00, all druggists and dealers, or sent express prepaid.
TROY CHEMICAL CO., TROY, N. Y.

Your Horse can work without pain while his sore breast is healing if you use MOORE BROTHERS'

For choice Red River Valley Farms. They pay railroad expenses if you buy from them. A few good bargains

360 acre farm, 4½ miles from Crookston, Minn, (a city of 7,000 inhabitants), and 2½ miles from the State Experimental Farm. This is a photograph of the buildings as they are today: House is 16x24 1½ stories with an L 14x22, and a wood shed in connection 20 ft. square, all on a brick foundation. Barn 28x48, with a lean to 16x48, sheeted both inside and out. Two granaries, one 14x80, and he other 14x42. The buildings are all w ll painted and in very good repair, and has a fine artesian well. Every acre of this farm in under a high state of cultivation, and is well drained by a slight ravine running through the farm, merely sufficient for self drainage. The soil is a rich deep black loam with a clay sub-soil, and in every respect is considered to be one of the best farms in that vicinity. Our price on this farm is $35.00 per acre.

This is a **320** acre farm about 2½ miles south of the city, this farm is quite well improved, has a very good house of about seven rooms, 1½ stories, barn large enough for ten head of horses, also a good granary, pasture and an artesian well, also has a good well at the house, good grove around the building. This is a very choice piece of land for the price $32.50,

160 acres north-east of the city; this is all hay land, and located in a German settlement, the surrounding country is nearly all under cultivation; we consider this a good piece of land for an investment, this could all be put under the plow, if desired, Price $19.00 per acre.

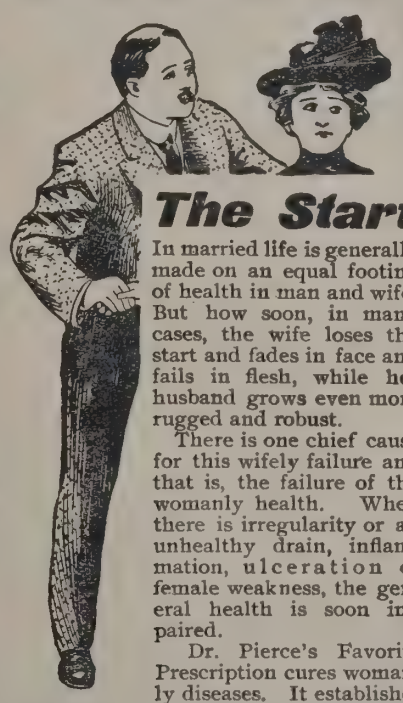
Selecting a Cow for Breeding Purposes.

ED. HOARD'S DAIRYMAN:—The success or non-success which attends the breeding of cattle is greatly influenced by the judgment exercised in the selection of the cattle which form the breeding herd. In this article, I intend to deal with the selection to the best of my ability; also to the treatment they should receive after they have been chosen. It is a well known fact and apparent to most people that there are two distinct types of cattle in almost every herd. One of these is best adapted for fattening purposes, while the other type lends itself more to the production of milk, although it also may be fattened, but not quite so readily as the first mentioned type. It is of this particular class that I will first speak; yet there are many features so common to both types of cattle, that part of this article will apply to the other class.

No matter what the breed of cattle may be, it is absolutely essential that none but the very best heifers should be retained for breeding purposes. We are all aware of the fact, that in the majority of cases, "like produces like," so it is absurd to expect first class progeny from moderate or inferior parents. So long as the latter are used, we shall continue to see a number of very plain animals being produced from the herds; and it is very difficult to conceive how such animals can leave a profit for feeding, when we take into consideration what amount of feed it requires to make this class of animals look anything like good, for even when they have condition on them they are nothing to look at.

Taking the present day prices of beef in this country, the average difference between choice animals and those of a secondary description amounts to about 5 per cent per cwt. (carcass weight), and as the former are always the more easily fattened of the two, it will at once be seen how greatly everything is in favor of the breeder who rears and feeds a good class of cattle. Even with the best of treatment, a lot of moderately bred and poor framed calves will never make the best class of cattle. Then as a general rule, they do not show that aptitude for rapid fattening, which characterizes their better bred rivals, but require longer keep and a greater amount of food to make them fit for the butcher's block.

I think from what I have said, one should be convinced that it pays best to select for breeding purposes only those animals which are likely to throw really good progeny. The additional capital involved to carry out this principle is almost fully returned by the enhanced value of the first offsprings.



A sum of eight or ten pounds will very often represent the difference in price between a heifer showing good quality and another showing moderate quality, both of the same age; so that the first animal bred from the former will recoup her owner for the extra price laid out on her purchase. The wisest course to pursue, from a fattener's point of view, when selecting heifers for breeding purposes, is to choose those animals which, while promising to be the right kind to throw produce of good fattening propensities, will also show some indications of being good milkers. Of course, great things cannot be expected from heifers during the first year, especially if they are not fed with a view to milk production. Yet they should yield sufficient milk to rear their own calves. In fact they should do a little more than that on proper feed, or there will be no likelihood of their being able to help in rearing additional calves during the next and following years.

However, when heifers can be obtained showing parts of these two qualitiies combined —milking propensities, together with the appearance of being adapted for fattening— it is a good and wise plan to procure them, so that should they prove indifferent breeders, they can either be sold to the butcher or for dairy purposes. From time to time we hear the question asked, "When is the best time to breed from heifers?" There are many who consider stinting young is the most profitable plan, whilst on the other hand, there are others who maintain that the physical development of the animal is arrested and doubtless it is, but whether to the detriment of the cow as a milker is a point to be seriously considered.

By hundreds of years of domestication the cow has largely increased her milk yielding capacity and I really believe that in this, as in other directions, the natural powers must be trained at an early period. An early assumption of the maternal functions tends to develop and increase the milk flow. If the animals are prevented from breeding young, then their natural tendency is to grow in the direction of producing beef rather than milk. When stinted at an early age the whole process of development is directed towards those parts relating to early motherhood. The parts required for the growth of the foetus, the hindquarters, the udder, escutcheon, milk veins—those make the prominent call on the system. But with the heifer kept to a later age for breeding, her development is pronounced in the growth and thickening of the neck, withers and forequarters with a general masculine appearance, and when she is delivered at a later period it is found that it takes longer to secure a milk flow, if ever it is attained.

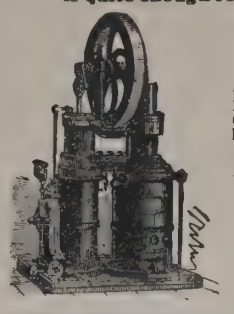
Taking the evidence as a whole, in this country, the majority of opinions are in favor of the heifer dropping her first calf at two years old. However, in going back to the selection of heifers for breeding purposes, when a sufficient number of heifers are not reared on the property, or when any other reason necessitates the purchase of young stock to augment the breeding herd, there is one important point that should always be kept in view when making a purchase, namely, the quality of land or food on to which they are to be brought. It is a great mistake to bring heifers that have been well fed and had every attention, on poor country, and expect them to keep in the same condition, without the same food and attention. Secondly, the climate should be taken into consideration, and the cattle to be bred should be a breed suitable to the climatic conditions, and the quality of the land and food. The heifers should show signs of good breeding (crossbreds cannot always be relied upon to throw good offspring) and have every appearance of being suitable for breeding a strong, healthy, rapid thriving class of cattle. Very strong, coarse loined animals should be avoided; but at the same time extreme fineness or weakness of bone must also be considered a fault.

The happy medium must here be sought for, but if it cannot be obtained it is better to choose those which are a trifle on the strong side, as they are, generally speaking, of a hardier constitution. Shapeliness of form is required,

The Start

In married life is generally made on an equal footing of health in man and wife. But how soon, in many cases, the wife loses the start and fades in face and fails in flesh, while her husband grows even more rugged and robust.

There is one chief cause for this wifely failure and that is, the failure of the womanly health. When there is irregularity or an unhealthy drain, inflammation, ulceration or female weakness, the general health is soon impaired.



Dr. Pierce's Favorite Prescription cures womanly diseases. It establishes regularity, dries unhealthy drains, heals inflammation and ulceration and cures female weakness. It makes weak women strong and sick women well.

"A little over a year ago I wrote to you for advice," says Mrs. Elizabeth J. Fisher, of Diana, W. Va. "You advised me to use Dr. Pierce's Favorite Prescription and 'Golden Medical Discovery,' which I did, and with the most happy result. I was troubled with female weakness and bearing-down pains. Had a very bad pain nearly all the time in my left side, nervousness and headache. Was so weak I could hardly walk across my room. Could not sit up only just a little while at a time. My husband got me some of Dr. Pierce's medicine and I began its use. Before I had taken two bottles I was able to help do my work. I used three bottles in all and it cured me. Now I do all my housework. It is the best medicine I ever used."

The Common Sense Medical Adviser, in paper covers, is sent *free* on receipt of 21 one-cent stamps to pay expense of mailing *only*. Address Dr. R. V. Pierce, Buffalo, N. Y.

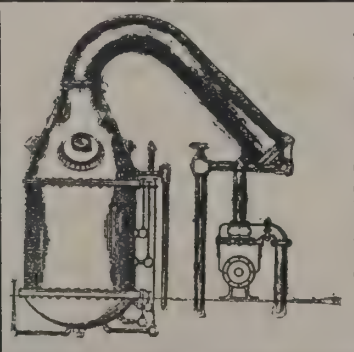
MRS. LEA'S MILK AND BUTTER PURIFIER.

Removes all Weed, Garlic, Vegetable and Animal odor and taint from the milk and in no way injures the cow to which it is fed.

WASHINGTON, D. C., May 27, 1901.



The trial of your "Purifier" made at my request, interests me very much and strengthens my conviction that this "Purifier" is an article which, if it continues to produce the results attained the present season, is destined to be of great importance and value in many dairying districts of this country.

[SIGNED] HENRY E. ALVORD,
Chief of Dairy Division, U. S. Department of Agriculture.

The use of our "MRS. LEA'S MILK AND BUTTER PURIFIER" is a necessity to producers of milk and butter when the pastures are at all infested with Garlic, Onions, Rye or Clover. It is a great saving, as the cows can be grazed, thereby saving largely in feed expenses. It always removes the taints when properly fed. The best dairies are using it largely and with profit. Try it and you will find it to your interest. For sale by The Dairymen's Supply Co., Philadelphia, Pa.; Farmers' Exchange Co, Belle Mead, N. J.; Cook & Brady, Middleton, Del; Filston Farm, Baltimore, Md.; Gardiner Dairy, Baltimore, Md.

Manufactured by VIRGINIA CATTLE FOOD COMPANY, Danville, Va.

Write Us for Prices and Further Information.

Milk Condensing Machine

I supply the most improved machinery and most successful processes for manufacturing all classes of condensed milk and evaporated cream. Factories built complete, put in operation and results guaranteed. If you are interested write for my new illustrated and descriptive catalogue. The only catalogue ever published on the subject.

R. R. ROGERS, Detroit, Mich.

I am not associated with any person, firm or company.

and it is of great importance. A broad, straight, level back always attracts the eye of a butcher, and to obtain this, we must always have cows and heifers which possess the same good quality. Deep, wide sprung and evenly covered ribs are essential, while the chest should be wide and deep.

The hind quarters should be broad and full, the skin soft and mellow and covered with plenty of fine, silky hair. Do not breed from heifers that have thick, heavy skins; in many cases they are not the best of thrivers, and are very seldom good milkers. A good head and neck helps the appearance of the animal very much, and are usually a reliable sign of a sound, robust constitution, without which success in breeding, and fattening cannot be looked for. The foregoing are some of the principal points to be attended to in choosing heifers from which to breed cattle for fattening purposes. It is very difficult to get all that we desire. Nevertheless, we should use our very best endeavors to obtain cattle of a type that will conform, as near as possible to the desired standard.

If we can only secure the class of cows that are suitable to the land and treatment they receive, and which will produce the right sort of cattle, we do not need to fear the result that will attend our breeding operations, and as far as meeting a profitable market for our cattle is concerned. The only way which we can hope to successfully meet the favor of the public, is to present nothing but the very best class of beef; and to be able to do this, we will first have to breed it. Before leaving the subject of selection, a few words about the sire to be used may not altogether prove out of place. I have previously stated that the heifers should show some signs of being fair milkers in order to do a little more than rear one calf each year.

Now, some means will have to be adopted to counteract these milking properties and to raise to the highest possible standard the propensity of rapid fattening in the offspring of these cows and heifers. There is but one way in which we can do this, and that is, to use only such sires as show by their breeding and general appearance, that they not only possess in themselves, but are likely to beget in their progeny, the essential qualities of being easily and rapidly fattened. This breeding should be closely looked into for the purpose of ascertaining whether he has decended from a breed well known for their fattening propensities, and unless the power to attain full growth at an early age, together with the disposition to lay on flesh at the same time, be a noted characteristic of his breeding, his use may not prove as beneficial as we desire. He should have all the good points mentioned as requisite to the heifers.

He must be well and evenly fleshed and his muscular appearance should be very marked in order that there may be greater liklihood of the progeny developing the fattening properties of their sire, instead of the milking qualities of the dam. To obtain good, strong, healthy calves the heifers should be in good condition when served. If in a thriving state, then it is almost certain that they will continue to thrive afterwards, which ensures the proper development of the foetus and therefore the dropping of a strong, healthy calf at proper time.

After the heifers are known to be in calf they must not be subjected to rough handling. It very often takes little to cause abortion, and most people, I think, know the nature of that malady to require warning against it. Excitement, bad or unclean food, over-driving or over-heating, bad water, etc., are all causes from which abortion may arise. With regard to the selection of cows and heifers from a milking point of view, I shall retain it for another issue, as too much space would be required to dwell on that subject in this article.

BUTTER TESTS AT NEW SOUTH WALES.
ROYAL AGRICULTURAL SHOW.

A very great amount of interest was taken in the Royal Champion butter fat test at this show, at which a prize of £100 was given under the following conditions: The competing cows could be of any breed and the prize has to be won three times by the same exhibitor, but not necessarily in succession or by the same exhibit. The percentage of butter fat to be determined by the Babcock test; the trial extends over three days. A special prize of £10-10, was also offered for the cow producing the largest quantity of commercial butter by the churn test, and another special of £6-6 for the cow giving the largest quantity of milk showing a butter fat percentage of not less than 3.25 per cent. All three prizes were competed for by the same lot of cows. Mr. A. Wealock's Spangle was first, giving a milk yield of 167 lbs., 8½ oz., and butter fat 5.870 lbs. The same owner's Stella was second; milk, 160 lbs., 10 oz., butter fat 5 870 lbs. The special for the greatest quantity of commercial butter was won by the same owner; butter 8.416 lbs. He was also second with 6 890 lbs. The special for the greatest quantity of milk was secured by same man, being both first and second. AUSTRALIA.

Relation of Milk to Cream.

ED. HOARD'S DAIRYMAN: —Please answer the following questions through your Inquiry column.

How many quarts of 25 per cent cream in 100 pounds of 4 per cent milk, also in 5 per cent milk. Please give formula.

Bernardsville, N. J. G. W. T.

In one hundred pounds of 4 per cent milk there will be 7.43 quarts of 25 per cent cream; in 100 lbs. of 5 per cent milk, 9.3 lbs. of 25 per cent cream. This is taking into account a loss of 0.1 per cent of fat in separation.

If we wish to put the above into a formula as requested it would be as follows: 25 (% fat in cream) : 3 9 (% fat in milk) : : 100 lbs. milk : x=15.6 lbs. of cream. 15.6÷2.1 (wt. of qt. of cream)= 7.43 qts., the amount of 25% cream in 100 lbs. 4 % milk.

THE MILWAUKEE LEADS

A Drive to Town

Will prove of particular interest to you if you will call on our local agents and inspect a "Milwaukee" Corn Harvester and Binder. The simple, automatic and effective mechanism in its construction will appeal to your appreciation of a thoroughly good machine. Successful in any corn grown—long, short, standing or lodged. It's made to cut, bundle and bind corn and,—it does it to perfection;—it has no superior.

Milwaukee Division
International Harvester Company of America
Milwaukee, Wis.

A full line of Binders, Mowers, Reapers, Corn Harvesters, Rakes, Sickle Grinders, Covers, Oil and Twine.

Big Bargains in Farm Supplies
First Class Material, Merchandise and Machinery at Sacrifice Prices.

Plumbing Supplies For Bath Room
Porcelain Bowl, Hardwood Seat and Tank, Nickel Plated flush and supply pipes, complete, each $10.00.
Cast Iron Bath Tube, Length 5 ft. Complete with full set nickel plated fittings, each $11.00. They are new goods, ask for free catalogue of our full line of plumbing supplies.

Steel Roofing
Strictly new, perfect, Semi-Hardened Steel Sheets, 7 feet wide, 6 feet long. The best Roofing, Siding or Ceiling you can use. We furnish nails free and paint roofing red two sides. Comes either flat, corrugated or V-crimped. Delivered free of all charges to all points in U.S. east of Mississippi R. and north of Ohio R. at $2.25 PER SQUARE
Prices to other points on application. A square means 100 square feet.

Barbed and Smooth Wire
Write for our prices on 2 and 4 point Barbed Wire, painted and galvanized; also, 65,000 pounds SMOOTH GALVANIZED WIRE SHORTS
Gauges: 10, 11, 12, 13 and 14. Price $1.40 per hundred lbs. We also handle other kinds, write us your wants.

Telephones at $5.00
Each one is guaranteed to be in perfect order before leaving our plant. We are able to offer you an instrument for $5.00 that would cost you twice as much elsewhere. We carry a full stock of supplies. Send for Phone Catalogue.

Cold Water or Ready Mixed Paints
Paints
We bought at Receiver's Sale from a leading paint house, a very large quantity of Cold Water Paints and Ready Mixed Paints. Equal in grade to any on the market.
Here is a Genuine Paint Bargain. Before placing your order, write us for our special prices. You can surely save money, without sacrificing quality.

Poultry Netting
A special lot of new galvanized No. 19 poultry netting while the supply lasts, at these prices. 150 running feet to bale.
12 inch..... $0.45 per bale.
18 inch..... 0.65 per bale.
30 inch..... 1.10 per bale.
36 inch..... 1.35 per bale.
42 inch..... 1.50 per bale.
Other grades at correspondingly low prices.

Wrought Iron Pipe
Steam, Gas or Water; sizes ⅛ to 12 in. diam. We have in stock 2,000,000 feet of Standard black wrought iron pipe, second hand. It is in good condition, complete with threads and couplings at following prices.
¼ inch at 1½ cents per foot.
⅜ inch at 2¼ cents per foot.
½ inch at 3½ cents per foot.
¾ inch at 4½ cents per foot.

Farm Forges $8.00
We bought several car loads of new Portable Forges at a low price. We have also for sale horseshoes, horseshoe nails, blacksmith tools of all kinds.
Hardware 500 doz. single bitted axes @ 35c. 175 doz. double bitted axes, 2d qual. @ 40c. 6,000 Dietz Lanterns, few slightly affected by water. Write for prices.

Gasoline Engine $70
2 HORSE POWER
Absolutely new; most modern type. Guaranteed, pumping jack & fixtures & fittings for $75. Without pumping jack $70.
Headquarters for Machinery
Our line of machinery supplies is almost unlimited. Complete stock of Saw Mills, Pumps, Sugar Machinery, etc.
And in fact everything in that line.

Building Material
LUMBER, SASH, DOORS, ETC.
We carry a complete stock of first class Building Material of all kinds. Send us your bill for estimate.
10 CARLOADS OF NEW DOORS AT $1,00 each
HARDWARE SUPPLIES
Write for our catalogue of builder's hardware. The per cent of the dealers profit we can save you will prove a revelation.

SEND FOR CATALOGUE NO. 20
We issue a complete illustrated catalogue containing prices of which the above are only a few samples. You ought to have a copy of this book in your home or office and we will send it upon request.

Quality of Cheese Influenced by Climate.

(Continued from page 362)

has been made in Kansas or Illinois than in Northern New York or Prince Edward Island is no criterion of the economy of the undertaking. When we consider that a cool, moist climate is essential to profitable cheese making we can easily conclude that the cheese belt of North America is by no means unlimited. Just now it happens that the best natural cheese making localities are the best butter making localities also, but this is owing to a condition. Vermont and New Hampshire are ideal cheese making states, but owing to their proximity to the best butter market in the world, Boston, they find it profitable to make butter rather than cheese.

A large part of Ontario is entirely unsuited to cheese making, yet, owing to the general demand for Canadian Cheddar, these localities are making cheese to the detriment of the industry, when they should be making butter instead. Proximity to good markets works against natural conditions. The dairy industry is badly divided as between cheese and butter. Localities are making butter that should be making cheese, and *vice versa*. A cool, moist climate, while it is the chiefest desideratum, is not, however, all. There must be pure water and sweet herbage. Sometimes it happens that in a cool, moist climate there is lots of low, marshy ground covered with acrid grasses and impure, nasty water. These conditions mitigate the production of either good butter or cheese. With coolness and moisture there must be pure running water and sweet, nutritious herbage. The more mountainous localities offer these desirable conditions.

The possibilities for enlargement of the cheese belt in America are, however, great. When the Rocky Mountain states become thickly settled, what conditions are there for the production of fine Cheddar cheese. Imagine the encouraging conditions of Colorado, for example, as a cheese producing state, with its mountain pastures, its clear, sparkling water, and its alfalfa fields, so like its Alpian cousin in Europe, where the finest cheese is made under similar natural conditions. The plain duty of the dairy associations and the Government Dairy Division is to encourage natural cheese districts to make cheese, and let those localities that do not enjoy such favored conditions, make the butter. The discovery of the new ferment, galactase, may qualify these conclusions, but time alone will have to prove this. J. A. M.

P. E. I.

Bran as a Fertilizer.

There is $13.00 worth of fertilizer in a ton of bran, in addition to the feeding value in it. Do you know that the whole Northwest—Minnesota, Dakota, Manitoba—in that whole territory the farmers are robbing their soil of its nitrogen, potash and phosphoric acid. When that wheat is ground up into flour there is a hundred dollars' worth of fertility to every carload of bran, The wheat stops in Minneapolis at the mills and the products go down into Ohio and New York.

If you and I were living on a river in which there were logs floating down past our town to another town, we would be inclined to stop those logs and manufacture them in our own town. But here we are sending down to New York and buying commercial fertilizers and shipping them a thousand miles into Wisconsin, when there is one hundred dollars' worth of fertilizer in a carload of bran which is available to us near at hand.

My friends, the reason that Wisconsin is where she is today is because we have been putting ten thousand carloads of Minneapolis bran over our farms. Do not worry about buying a carload of bran. Davenport, down in Iowa, does not think it a disgrace to buy saw logs and make lumber out of them. If you can make $3 or $5, or $10 on a ton of bran; if you can have some butter to sell and about $13 worth of fertility for every ton you buy, you are ahead of the game. If those people want to go on raising wheat and taking millions of dollars' worth of fertility out of their lands, let us be wise enough to take advantage of it to enrich our lands. Let us take advantage of it as long as they are willing to let us. Let us stop that bran in Wisconsin, stop the middlings and the Iowa corn and send our butter, cheese and eggs on east. —PROF. W. A. HENRY.

$5.00 BUGGY Offer — Most Liberal Proposition Ever Made!

FROM OUR OWN FACTORY

"XX FLYER"

$38.50 F. O. B. CHICAGO

Built to Your Order With Your Monogram on Seat Riser

"The buggy has arrived. We consider it a bargain, saving us at least $25.00 in price." — E. J. PHILLIPS & BROS., Round Mountain, California.

1000 sold since April 1st. — Remember it is ours if it does not please you.

YOUR BUGGY is built *exclusively for YOU*. We have a large stock of bodies, wheels, gears and shafts, all in lead and oil, ready to be finished *to your order* by the best mechanics the market affords. The price we quote is the cost of material, the labor of making and a small profit for our factory. Such opportunities are not offered every day.

YOU SEND $5.00 with your order and the balance 10 days before you want it shipped. It goes direct to you from our finishing rooms in all of its original beauty. ILLUSTRATIONS, DESCRIPTION and full information with *Free Vehicle Catalogue* sent upon request. Send postal today. An unusual offer. Do not miss it.

EMPIRE

EASY RUNNING..... Cream Separators

It's a broad claim we make but **We Deliver the Goods**

More up-to-date creamerymen are pushing the Empire Cream Separator today than any other separator on the market. Why?

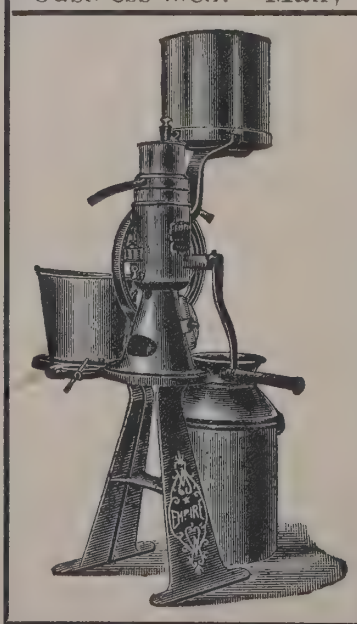
More up to-date dairymen delivering cream to creameries are buying the Empire Cream Separator today than any other separator on the market. Why?

More farmers are perfectly satisfied with the Empire Cream Separator today than with any other separator on the market. Why?

It's Altogether a Question of Merit.

We do not expect to sell a separator to every farmer in the land. We do not expect every creamery to take up the sale of the Empire. We could not accommodate all of them either with territory or machines. We know some of them are tied up with other manufacturers and cannot break loose, no matter how much they want to.

We do not bull-doze creamerymen. We do not threaten "to ruin them" if they sell another machine. We do not appeal for patronage on any grounds other than simple merit. We can take that position because the



Empire Cream Separator

Does the Business.

We have never yet known a live creameryman who has thoroughly investigated the merits of the several hand cream separators on the market, to undertake the sale of another machine if he could get an agency for the Empire. Here are a few of the wide-awake fellows who are selling the Empire:

Hygeia Creamery Company, Omaha, Neb.
Geyer Creamery Co., Storm Lake, Ia.
Tri-State Creamery Co., Chicago.
J. D. Bickel Produce Co., McGregor, Ia.
Jahnke Creamery Co., Watertown, Wis.
J. P. Baden Produce Co., Winfield, Kan.
Blue Valley Creamery Co., St. Joseph, Mo.
Central Michigan Produce Co., Alma, Mich.
The Dodge Creameries of Wisconsin and Illinois.
Des Moines Creamery Co., Des Moines, Ia.
Longmont Creamery Company, Denver, Col.
Cedar Valley Creamery Co., Cedar Rapids, Ia.
Ernest Karow, De Forest, Wis.
C. J. Dodge, Lodi, Wis.
Osseo Creamery Co., Osseo, Wis.
Comfort Produce Co., Bad Axe, Mich.
A. Nolting & Sons, Elgin, Ill.
Oakdale Dairy, Fort Dodge, Ia.
Townsend Creamery Company, Portland, Ore.
Mason City Cream Co., Mason City, Ia.

Many of the above institutions were users of other makes of power machines—all of them were most vigorously canvassed by other manufacturers—all of them have heard the stereotyped story of "ten times as many machines in use as all other makes combined," and about "protecting patents" which have expired and which no one wants to use. They have been bull-dozed and have listened to threats that "another creamery would be started across the road;" they have been offered antiquated, complicated, "patent protected" separators at as low and lower prices than they are now paying for the Empire, but they chose the Empire on a merit basis alone after a thorough investigation. Look up these companies who handle the Empire. They are clean, reputable business men. Many of them are selling from 200 to 400 separators per month. In the state of Kansas alone more than two thousand Empires were placed during the past year. The volume of business done by creameries using the Empire separators is double that of the aggregate business done by any competing machine through like channels. Investigate this statement. The Empire Separators are now being manufactured at the rate of 100 per day and still the demand is not being fully supplied. The reason is simply this:

When an Empire Separator is placed in a community, a dozen always follow it.

It is a machine that sells itself. It is so much simpler in construction, so much more easily operated; so much more easily cleaned; and gives so much less trouble that most farmers say it is worth twice as much as any other separator they ever saw. Don't be misled. Investigate for yourself. Examine the Empire, its work and its record, and then if you don't decide that it's the best separator in existence we'll not have another word to say. We want you to satisfy yourself **before you buy.** We'll guarantee the Empire will keep you satisfied after you buy.

EMPIRE CREAM SEPARATOR COMPANY,

Bloomfield, New Jersey. **Chicago, Illinois.**

The Empire has more late improvements and labor saving conveniences, covered by late patents, than any other separator made. That's why it keeps so far in the lead.

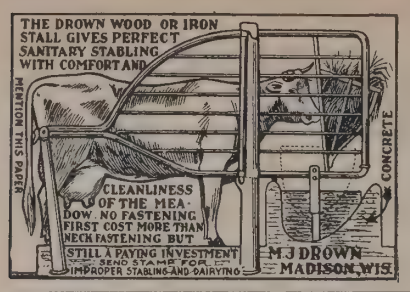
Milk Condensing Machine I supply the most improved machinery and most successful processes for manufacturing all classes of condensed milk and evaporated cream. Factories built complete, put in operation and results guaranteed. If you are interested write for my new illustrated and descriptive catalogue. The only catalogue ever published on the subject.
R. R. ROGERS, Detroit, Mich.
I am not associated with any person, firm or company.

A BUCKET FULL OF FILTH

We would like to look at the dairyman who would take a bucket half full of filth, bacteria, disease germs, barnyard refuse, etc., and use it as a milk bucket in which to do the morning's milking? You wouldn't do it,—of course you wouldn't and we don't think you know of anyone who would. But say! right here let us ask you if it is very much better to run fresh warm milk through a "bucket bowl" separator? What is the difference whether it goes into a filthy bucket or into a filthy "bucket bowl?" There are just two types of separator bowls, the **Tubular** bowl and the "bucket bowls." Only one **Tubular** bowl but a dozen or more "bucket bowls"; buckets full of cones, buckets full of plates, buckets full of discs, buckets full of blades, buckets full of contraptions that cannot be kept clean and that soon become so filthy that you must hold your nose when using them. The warm weather is coming on and if you will just get a whiff of the "disky flavor" that comes from one of these "bucket bowls" you will know what we mean. Don't let anyone sell you a bucket full of filth.



Examine the simple, light running TUBULAR DAIRY SEPARATOR. Just one piece in the bowl, as easy to clean as a tin cup. Compare it with any other separator and see if your good sense will permit you to buy a "bucket bowl" machine. Don't take anybody's word for it, look and see. The Tubular will stand the test, but how about the others?

The Next N. C. B. Meeting will be at Sioux Falls, S. D.

ED. HOARD'S DAIRYMAN:—The Executive Committee met in St. Louis, Mo., May 18-19 to decide on the location for the 11th Annual Convention of the National Creamery Buttermakers' Association. All members were present and after carefully considering the propositions, made by several candidates for the meeting, it was decided that the offer from Sioux Falls, South Dakota, as made to the committee at Cedar Rapids, Feb. 4th be accepted. The offer is as follows:

Sioux Falls subscribes $2,500 in cash towards the premium fund, free halls for all purposes and free entertainment of the officers of the Association.

It will be remembered that Sioux Falls took excellent care of the large numbers who attended the 6th Annual Convention, and as the Cataract House, which was destroyed by fire soon after that convention, has been rebuilt almost twice as large, and is run in a first-class manner by an exceptionally efficient landlord, there need be no apprehension about securing first-class accomodations. Besides the Cataract Hotel, there are a number of other well conducted hotels.

In explanation to those who were interested in having the meeting taken to Buffalo, we wish to say, that Buffalo was afforded every opportunity; your Secretary even made a trip to that city, and while the hotel situation, as well as the convention hall, was very satisfactory, and while the representatives of the Convention Bureau and Manufacturers Association showed him every courtesy, he was unable to get any definite offer as to a financial contribution, therefore it was impossible for the Committee to consider Buffalo at all.

Hoping that those interested in the creamery industry will support us in our efforts of making the 11th Annual the very best convention since the organizing of this Association, we remain,

Pearl Millet, or Pencilaria.

The United States Department of Agriculture has recently issued *Farmers' Bulletin No. 168*, which answers questions which we are frequently asked concerning pencilaria. We quote from it, as follows:

"The recent effort on the part of certain seedsmen in this country to revive interest in pearl millet by offering it under new and attractive names and at very high prices renders it desirable that a statement concern ng its cultivation and uses should be made for the information of those who may be interested in green fodder crops. This crop has been grown more or less in this country for thirty years. It is known that under favorable conditions, particularly in the southern states, it yields a large amount of green fodder. If utilized before the plant is mature the fodder is palatable, but if the plant be allowed to mature it becomes so woody as to be of little value. The most important difficulty in connection with its cultivation lies in the fact that the seed is rather unreliable. Most of those who have experimented with this crop have failed to secure a satisfactory stand. The department of agriculture has grown the crop experimentally for a number of years, and last year obtained seed from all the seedsmen in this country from whom it could be had, not only under the name of pearl millet, but under the name of pencilaria and Mand's WonderForage Plant, and they all proved to be practically the same thing. Consequently farmers who desire to try this crop are advised to purchase the seed under the name of pearl millet, as under this old and well established name it is sold cheaper than under the new names."

This same plant has been exploited in Germany under the name of Peruilaria, and sold at first at the rate of $69 per pound. The bulletin further states that of the seventy-four seedsmen whose catalogues were examined recently, thirty-five offered the plant for sale under some one or more of its names, six under the name of Mand's Wonder Forage Plant, four as pencilaria, and twenty-five as pearl millet only. Three have stated that pencilaria and Mand's Wonder Forage Plant were only new names for the old pearl millet. The price varies from 12 cents to $1.50 per pound.

SAVE 20 CENTS PER SHEEP on every sheep you shear with
STEWART'S PATENT
SHEEP SHEARING MACHINE
The day of the old fashioned hand shears is past. No owner of 10 sheep or more can afford to shear by hand, even though the work be done for nothing. Don't butcher your sheep. Shear with this machine and get ONE POUND WOOL EXTRA PER HEAD. It will more than cover the cost of shearing

MRS. LEA'S MILK AND BUTTER PURIFIER.

Removes all Weed, Garlic, Vegetable and Animal odor and taint from the milk and in no way injures the cow to which it is fed.

WASHINGTON, D. C., May 27, 1901.
The trial of your "Purifier" made at my request, interests me very much and strengthens my conviction that this "Purifier" is an article which, if it continues to produce the results attained the present season, is destined to be of great importance and value in many dairying districts of this country.
[SIGNED] HENRY E. ALVORD,
Chief of Dairy Division, U. S. Department of Agriculture.

The use of our "MRS. LEA'S MILK AND BUTTER PURIFIER" is a necessity to producers of milk and butter when the pastures are at all infested with Garlic, Onions, Rye or Clover. It is a great saving, as the cows can be grazed, thereby saving largely in feed expenses. It always removes the taints when properly fed. The best dairies are using it largely and with profit. Try it and you will find it to your interest. For sale by The Dairymen's Supply Co., Philadelphia, Pa.; Farmers' Exchange Co, Belle Mead, N. J.; Cook & Brady, Middleton, Del; Filston Farm, Baltimore, Md.; Gardiner Dairy, Baltimore, Md.

The Physiology of Milk Secretion.

(Read Before the Nebraska Dairymen's Association by John J. Repp.)

Milk is the normal secretion of the mammary gland of females of the order mammalia. In this paper, however, only cow's milk will be considered. It is white, opaque, slightly sweet in taste, alkaline or amphoteric in reaction, and has a characteristic odor. The specific gravity is 1.029 to 1.033. It is composed approximately of water 87%, sugar 5%, fat 4% casein and albumen 3½% and salts ½%

Each of these constituents is in itself highly complex in composition. The component parts are disposed as follows: The casein, albumen, sugar and salts are in solution in the water making a solution called serum. The fat is in suspension in the serum. The fat is divided into very minute globules or particles 1-2500 to 1-5000 of an inch in diameter, each of which is surrounded by a thin sheath of casein, which prevents a coalescence of the globules.

In the process of churning, the casein envelopes are broken and the globules of fat collect in masses which we call butter. Milk is ordinarily considered a solution, but it is, strictly speaking, an emulsion as the oil globules are only in suspension and not in solution. Under the high power of the microscope the oil droplets appear as highly refractive bodies floating in a clear fluid.

As stated at the outset, milk is a secretion of the mammary gland. This gland is a dependency of the skin, and is a member of the group of glandular structures known as compound sac ular, or racemose glands. A cow has four such glands which, combined, form what is popularly known as a bag, or udder. Each gland is composed of 15 or 20 distinct lobes which are held together by connective tissue so as to form a single conical mass. Each lobe is subdivided by penetrating septa of fibrous and fatty tissue into numerous lobules which are again subdivided into the individual sacs called acini. The acini are very small, barely visible to the naked eye, and each one is lined by numerous columnar epithelial cells. These cells are microscopic in size, varying from 1-1000 to 1-200 of an inch in diameter. Each acinus has a minute tubular duct leading from it. These small ducts unite to form larger ones which constitute the ducts of the lobules. These larger ducts still further unite to form the common lactiferous, or milk-bearing, canals which in turn empty into the large cavities at the lower part of the gland called milk sinuses. The ducts and milk sinuses are lined with epithelium.

By way of illustration, in order to make the description which I have given more clear, I will ask you to imagine a very prolific grape vine with fifteen or twenty bunches of grapes hanging close together. This would represent in a rough way a mammary gland, each one of the bunches would figure as a lobule, and each grape on a bunch an acinus. Now conceive each grape hollowed out almost to the hull and then lined with small column-like bodies. These bodies would represent the cells. The stem of each individual grape will represent the small, intralobular duct which conveys the secretion out from the little sack in which it is formed. The main stem of the bunch and the principal branch upon which the various bunches hang, typify the interlobular and the common excretory canals. The fibrous and fatty tissue between the acini and lobules of the gland may be likened to the air which everywhere fills the interstices of the various parts of the vineful of grapes.

The milk sinus of which I spoke above has in each gland a capacity of about one pint, making two quarts for the entire udder. In these sinuses, together with

A PRINCE EDWARDS ISLAND DAIRYMAN.

J. A. McDona'd, of Hermanville, P. E. I. Better known to readers of the Dairyman as J. A. M.

the ducts and acini, the milk which is secreted during the intervals of milking or suckling is stored up. The milk finds its way to the exterior during the milking process through an extension of the milk-forming apparatus called the mamilla, nipple, or teat, which is pierced by a canal to admit of the passage of the fluid.

The condition of the mammary gland varies with the different periods of life, as well as under different conditions. In early life and up to the time when the first period of pregnancy is progressing the gland is usually in a rudimentary state, consisting then chiefly of fibrous and fatty tissue. The functional elements, namely the cells, acini and ducts are a solid, unexpanded, inactive mass. Near the termination of the period of gestation these essential parts of these organs undergo a rapid development so as to be in a condition for active work at the proper time. During this preparatory stage the connective tissue septa become reduced to quite thin partitions and the secreting tissues greatly predominate. After a considerable, but varying, period of lactation the functional parts of the organ become less and less conspicuous until at last their actions cease altogether. This we call "going dry." Then, unless another period of gestation intervenes, this state of atrophy becomes permanent. Thus there is seen to be a close sympathy between the organs of generation and those of lactation.

The mammary glands are well supplied with blood vessels, nerves and lymphatics. The blood supply finds its way to the glands through the external pudic artery. It is carried along the ducts in the connective tissues by small vessels and finally right up to the epithelial cells by the capillary vessels. The blood is conveyed from the udder by the subcutaneous abdominal, or milk, veins which pass forward along the abdomen just under the skin to the region of the sternum where they penetrate the abdominal wall and enter the thorax by numerous perforations, several of which are so large that they may readily be felt by the end of the finger. These openings are popularly called "milk-pores" or "milk-fountains," names which are, however, not very appropriate. The size of these openings and of the milk vein are by some considered an evidence of capacity for milk production, but such an inference is of doubtful propriety and often misleading. The lymphatics follow pretty closely the course of the blood vessels.

The nerves come from the first pair of the lumbar plexus and ramify to the walls of the acini.

Allow me now to consider briefly the exact mechanism of milk secretion. The epithelial cells to which I have already directed your attention with their blood and nerve supply are the important factors in milk secretion. All other things are subordinate. Upon the development depends the quality and quantity of the secretion. The cow must not be viewed as a receptacle into which so much water and solid food may be introduced at one end, while from the other end so much milk may be drawn. Without denying the influence of other things it is safe to conclude that most depends upon the capacity for work possessed by the cells of the gland.

The epithelial cells, which are the working part of the gland and which, as I have already pointed out, line the innumerable little sacs and tubes which make up the gland, are little masses of proteid substance, known as protoplasm, enclosed by a thin membranous wall. Near the centre of the cell is a small particle of more condensed protoplasm called the nucleus. As the time of calving approaches these cells multiply rapidly and are cast off into the acinus. In addition large, white blood cells, called leukocytes, find their way into the acini. These leukocytes take up fat droplets which are secreted by the epithelial cells and tubules. When calving occurs, watery materials are added to these accumulated cells and the resulting fluid is known as colostrum. The large leukocytes with fat droplets within them are known as colostrum corpuscles, and are a prominent feature of the fluid when viewed under the microscope. Gradually the character of the secretion changes until about the end of the fourth day it has the true character of milk. While at rest the epithelial cells are small and granular. As activity sets in and advances, the cells become increased in size, the granules disappear and the cells become filled with secretion. The outer part of the cell, between the nucleus and the lumen of the tubule undergoes fatty change and is cast off to constitute part of the solids of the milk. The remaining part of the cell which contains the nucleus, then immediately undergoes a regenerative process so that soon the cell is restored to its full size and capacity for work.

This cycle of degeneration and regeneration may be repeated a number of times in each cell before it finally dies and is cast off. In the process of milk secretion the whole cell does not degenerate, only the outer part of it. The fat, casein, albumen and milk sugar are formed by this process of partial degeneration of the cell. The water and salts, on the other hand, are the results of simple transudation, or filtration, from the blood and lymph capillaries which surround the cells. As evidence that the formation of casein and sugar are not a mere filtrate we have the fact they do not exist preformed in the blood or lymph even up to the point at which these fluids come into contact with the cell. Fat exists in the blood but only in very small quantities. The total amount of fat in the blood of a cow would not equal the amount of fat removed from the udder at one milking. It is evident, therefore, that the fat, sugar, and casein, the greater part of the bulk of solids in milk, are the product of special cell activity.

It is essential also to note the greater part of the milk is secreted during the the act of suckling or milking. It has been shown that the milk sinuses will hold about two quarts of milk. Allowing a like amount for the capacity of the acini and ducts and it is seen that the total capacity of the udder is about one gallon. This is not more than a third or a fourth of what a good cow will produce at a milking or suckling. In the intervals of withdrawal of milk from the udder the gland cells are in a state of partial rest, but as soon as withdrawal is begun the cells, which are under direct control of the nerves and blood supply, are excited to great activity, with the result that the milk is produced in large quantities. An additional evidence that in the intervals of milking the cells are only slightly active, is found in the fact that the milk which is stored up during these intervals, is very watery and poor in fat. During these rest periods the transudation of water is out of proportion to the production of solids especially fat which is the direct result of cell activity.

Knowing, then, that the principal constituents of milk are the direct outcome of the cellular activity of the mammary gland we are prepared to appreciate the great importance of proper development of this gland. As a rule a good udder is one of generous size, but this is not always the case. The fibrous and fatty tissue which make up the supporting framework of the udder, may be of such excessive development as to contribute a large part of the bulk. Such an udder, though large, is apt to be ridged and unyielding and to be reduced only slightly in size by milking. I would consider that pliability of the udder after the milk has been withdrawn is a characteristic of great importance in determining the value of an udder as a milk producer.

More valuable, however, than any external appearance is the application to each individual cow in a herd of some test of total solids or of fat alone. Owing to the fact that, as a general rule, the other solids of milk maintain a tolerably constant ratio to the fat, it is a common practice to judge of the value of a dairy cow by the percentage of fat which her milk contains. For the determination of fat, the Babcock test is used almost exclusively for commercial testing. There are other methods which are more accurate, but on account of the difficulty which attends their use they are employed only in the laboratory. Before a dairyman can lay claim to an accurate knowledge of the producing powers of the individuals of his herd he must have applied a fat test to each of them a sufficient number of times to detect the fluctuations which ordinarily occur in every cow.

In breeding or purchasing dairy cows, choice may be made from one or more of the well known dairy breeds, or from a good milking strain of the beef type. Many grade cows of unknown breeding are excellent dairy animals, and it is profitable to search for and find them. The day is coming when dairy cows will be bought and sold upon the basis of response to the Babcock test. This is an ideal which may soon be reached if it is striven for.

The manner of feeding also has an important bearing upon milk secretion. Of course, it is true that if a cow has a poorly developed milk secreting apparatus no method of feeding will make a good cow of her. Recent tests at experiment stations have shown that the fat content of milk can not be much increased by feeding methods. There is a maximum limit of production, dependent upon the gland development, peculiar to each individual cow beyond which she cannot be forced by any kind of feeding. However, any cow, whether good or bad, that has been poorly fed can be much improved by proper food given in sufficient quantity.

Water, of all foods, has the greatest influence upon the composition of milk. Cows should have as much water as they will drink, not less frequently than twice a day. In winter it should be heated so as to remove the chill. The water should always be pure. The drinking of impure water not only has a deleterious effect upon the milk, but it leads to parasitic infestation which lowers the vitality and lessens the milk flow. Of the inorganic foods, perhaps the only one that needs to be supplied is common salt. The other inorganic constituents are present in sufficient quantities in the food and water.

In connection with organic food stuffs attention is called to the fact that the various food elements, viz: proteids, carbohydrates and hydrocarbons, are not transferred directly from the food to the milk. These food principles first undergo chemical change in the process of digestion and later on, as has already been pointed out, they undergo chemical change in the epithelial cells of the mammary gland.

It is well known that starches, sugars and proteids are converted into fats. Also that one kind of fat is changed into another kind. The casein of the milk is supposed to be produced from the albumen of the cell and probably has its origin in the proteid food principle. The

origin of milk-sugar has not been clearly demonstrated, but the observation that the amount of sugar is not decreased by withholding carbohydrates, tends to show that it may originate from the proteids or even from the fats. That fats are produced from starches and sugars is evidenced by an experiment at the Geneva Station in which a cow that received in 95 days, food containing only 5.7 pounds of fat, produced during that time 62.9 pounds of butter fat and at the same time gained flesh, so the fat of the milk could not have been obtained from the body. Neither was it all obtained from the protein of the food, for only enough protein was given to produce about one-half of the fat which the milk contained. Other experiments confirmed the finding in case of this one cow.

The relation of milk-secretion to feeding is so intricate that it has been thus far impossible to put it upon a basis that is entirely scientific; it is, in a measure, empirical. The best guide we have in feeding is the nutritive ratio, with the food supplied in sufficient quantities. By nutritive ratio is meant the ratio of the proteids to the carbodydrates and hydrocarbons combined. In dairy cows it has been found by experimentation that the best results are obtained when the nutritive ratio is about 1 to 6 or 7. The quantity of food depends chiefly upon the size of the cow and the capacity of the milk glands for secretion. The dairyman is always repaid for generous feeding. Green, succulent food, in the form of ensilage, pasture and soiling crops, can be furnished every day in the year, and is invaluable.

Milk cows should be well protected against both the extreme heat of summer and the extreme cold of winter. At the same time proper ventilation should be provided. This is of the utmost importance and is frequently overlooked. While it is doubtless true that a cow kept at perfect rest will, other things being equal, give the greatest quantity of milk, yet considerations of health forbid such forcing and require that the cow be given moderate exercise in the open air. Undue exertion should be avoided.

As the milk glands are under direct control of the nervous system, any conditions which affect the nervous system, will react upon the milk-producing glands. Any undue disturbance of the normal distribution of the nervous force will divert some of the blood supply from the milk glands to some other part of the body and thus diminish the milk flow. The well known phenomenon of "not giving down" the milk is the result of lack of nervous tone in the gland brought about by some sort of excitement. The udder is not a container in which the milk is ready stored up at milking time, but an organ in which, as has already been pointed out, the greater part of the milk is elaborated while milking or suckling is in progress by virtue of the agitation produced. Unless the cow is in perfect repose this secretion will not take place normally. The lesson to be derived from this is that the cow should be treated with the greatest gentleness and be otherwise kept free from excitement, especially during the time of milking or suckling.

The Results in one Maritime Dairy.

For some issues past we have been recounting the successes and failures of farmers all over Eastern Canada, but have never before given the figures for a year from a real live Maritime dairyman.

A year ago, Mr. Fred W. Davidson, Anagance, Kings Co., N. B., submitted to us an article showing how much more money he had made in his dairy by sending his milk to the creamery, retaining the skim milk on the farm. This statement was so excellent a showing that we at once asked him to let us have his next year's figures, and as his year closes on March 15th, we are now in receipt of a rough draft from his books and a request "to write it up for him—he is too busy."

Well, to begin with, we always like a little history. Fred Davidson is a young man, possibly 40, born on a farm in upper Kings and now resident at Portage, four miles south of Anagance Station and practically on the boundary between this county and Westmorland. We are not sure how much land there is in the farm but something near 45 acres is under cultivation and the rest is divided between pasture and woodland. It is not what appeals to one as a good farm, being hilly and light and somewhat springy—just such a farm as hundreds of others, hard to manure and very hard to maintain.

The Davidsons have been a family of beef-cattle feeders, some of New Brunswick's early Herefords being theirs. It is, however, a difficult proposition to make beef pay on farms such as we have described, because it is difficult to carry them through winter without their eating their heads off.

In his early days Fred W. was a clerk in a store somewhere. We don't know where and it makes no difference. Mercantile life had no charm for him and he never quite lost sight of the farm up among the hills, across the road from the Episcopalian meeting house. In addition, however, to a fair knowledge of bookkeeping, his experience taught him the true relationship between profit and loss, a point which, on his return to the farm, he began at once to figure closely upon. It did not take him long to see that the thing would not pay unless something different was done, for from raising less and less feed on the farm they were now unable to get a catch of clover.

A change was made after much study. As we were laconically told "he got something that ate less"—he got some Jerseys and he started in to make butter, for sale in St. John. If memory serves us right, he once supplied the Royal Hotel. The business prospered. His feed went further. His cash returns were greater. His manure pile was a carefelly guarded spot. By using his skim milk profitably he not only had good calves but plenty of pork and, in fact, he came very near making the traditional two blades of grass grow.

From the beginning, every available new idea was put into effect. The new barn was light and airy, with a large manure cellar. Then came a hand separator, followed by a series of trips to the nearest Babcock test until the skimming was down fine and a knowledge of what each cow was doing, obtained. Then came a silo, and the corn growing has never failed him. This all made more cows possible and Mr. D. envolved his well-known slogan: "Raise more corn, to keep more cows, to make more manure, to raise more corn, to keep more cows." Gradually the number of cows rose to 23. Then came the parting of the ways.

On a farm where so intensive tillage must be pursued, it means much work. The family are all young and the scarcity of hired help became an alarming perplexity. Between heavy cropping on a farm where work was carried on at a disadvantage, and making butter at home, no one man could carry it all. And anyway a few bad customers too seriously affects one's profits. The business was paying too well to be dropped and after much more study it was decided to send the cream by rail to Sussex creamery, still retaining the skim milk. This meant one great saving and the event has proven it to be much more profitable than the old method of butter making when farm work was crowding and then taking chances on collections.

The next move was to get a water supply installed and a windmlll was placed on the barn with a pump in the basement to raise water from the creek which ran behind the old meeting house previously referred to. In addition to this the mill pulps the roots and the boys are happy. The final move was made in the purchase of a manure spreader and since then the expenditure for hired help has been much reduced, while, in the face of all that, the report of Sussex creamery finds Davidson's Jerseys during 1902 heading the list of 137 patrons with 16,347 pounds of cream which gave 4,779 97 pounds butter fat and brought him $1129.15 in "elegant hard money," to use the phrase of a well-known cream separator man.

So much for the past of this farm and herd—no, not quite, either. We should repeat what their owner has already told us, that the aim has been to have all cows come in in the early fall and that the land is devoted as far as possible to the production of corn and clover hay with the oats. Mill feeds are bought in sufficiently large quantities to make the price right.

Now for the statement:

RECEIPTS.		EXPENDITURES.	
Cash from creamery	$1267.65	Feed—cows	$383.56
Butter made at home at creamery prices	33.37	pigs	202.78
Pork sold	470.26	Seed grain	37.27
Beef sold	60 00	Hired help	70.00
		Taxes	33.78
		Insurance	10.00
		Bal. on hand	1093.89
	$1831.28		$1831.28

In the way of additional figures we are told that the skim milk reached the round total of 50 tons and the pork averaged $7.44 at the autumn sales and $7.56 this spring.

As we have said, the above is a cash showing, and, in our judgment, a right good one, the correctness of which is questioned by no man who knows Davidson. Taking the average, it is seen that he made a gross return of $56.56 per cow and there are heifers among the lot too. We question if the Ontario farmer we first quoted can beat the average, when the allowances are made, for we know his tax bill and hired help bill would both be at least three times greater than Mr. D's. Maritime farmers may kick, but they don't know the first principles of paying taxes.

We have been turning over mentally how to average the improvement of the land. It is a great consideration, but the only measure of its value is the gradual and continuous increase in the number of cows kept. More clover, more manure and more grains are responsible for this.

The pork question has a great interest for us. Be it known that this is the same Mr. Davidson who made his skim milk worth 42 cents per hundred in years gone by. These pigs are Yorkshires and a good lengthy sort at that. From the $470.26 received from pork sales, take the $202.78 paid for their grain and then take out $5 for roots fed, for we are giving the unbeliever in pork no chance to turn, Mr. Davidson is positive that not over two and one-half tons of turnips were used. That leaves us $272.48 for the skim milk, an average of twenty-seven and one-quarter cents per hundred, or $5.45 per ton. It must be understood that if this pork had been sold when it was bringing $9.25 per hundred in St. John, a difference would again be seen of something between $30 and $35 on the 26 hogs sold at $7.56. And it should further be explained that they were fed on corn meal, a ration which not many of our farmers would be compelled to use. Take it as it is and we should like to know how else a man can get 27¼ cents for a hundred of skim milk, and return the manure of 26 pigs to go to the upbuilding of a needy farm.

We like these statements. They show us where we are and what can be done. We scarcely expect Mr. Davidson's thanks for giving these datails because the slip he sent us with his figures might have been put in as it was and doubtless intended so to be. But this man's work is not beyond the attainments of any man and we know that many others have been watching him since the day he addressed the Dairymen's Association at Fredericton three years since, and his success in corn growing has been the subject of much other experiment in the same direction.

We should like to have his picture to show our readers, but he declines to sit and there in none in existence. We had one of the barn and herd and spoiled the plate, but we shall repeat that attempt when next we visit Portage—a trip that should be made by every one who experiences an occasional doubt of our agricultural future and can enjoy a good trout stream.—*Maritime Farmer.*

The Care of Springers.

Protein and Butter Fat.

ED. HOARD'S DAIRYMAN: — Though winter dairying has made wonderful progress in late years, to the great advantage of dairy farming as a business, for it has been many times shown that the winter dairy cow which has calved in the fall, gives a profit of from ten to fifteen dollars over that of her spring-calved sister, yet, as fall calving and winter dairying call for a larger amount of skill and care than does summer dairying, the winter dairymen are largely in the minority, and will be, no doubt, for a long time to come. Winter laying in poultry, winter lamb raising and winter horse raising have been shown to be immeasurably more profitable than the same pursued in summer, and still how few there are, comparatively speaking, who change to winter. Winter dairying, however, has made rapid progress in the last ten years and it would be idle, from a knowledge of the past, to attempt to prophesy what the next decade may bring forth. The large majority of cows still calve in the spring, and of these it is of more importance to speak.

Most people who keep a dairy of cows due to calve in the months of March, April and May, pay very little attention to the cows until the period of calving has arrived, then they fuss about them and fret them and frequently lose a good

Peculiar To Itself

deal of time of themselves and the use of the cow by retention of the placenta and other ills. A cow, that has been neglected by its owner during the winter, and receiving no grain food up to the time of calving, will not give that measure of profit when she comes in milk that she would if given good care and food some time previous to parturition.

Ordinarily a cow does fairly well up to within a month of calving, without any meal or grain, provided her other feed is fairly succulent and nourishing. Some men take their cows fairly well through the winter on nothing but straw and turnips. Succulence, either in ensilage or roots is of the first importance. A daily winter ration of well cured oat straw, peas and oat straw, or the same made into hay with forty pounds of turnips or mangels make an excellent and cheap ration up to within a month of calving.

Beginning, however, about a month before the cow is due, a small grain ration should be given daily. I am sure that a mixture of oats, barley and peas, grown together—a crop which every dairyman should endeavor to grow—with wheat bran, half and half by weight, will be found to be both cheap and salutary. Begin with a small daily allowance of this mixture, in addition to the regular feeding, and gradually increase the grain allowance so that up to within a week of calving, the cow is getting six or eight pounds, or as much as the cow would receive with a full flow of milk.

The bowels must be watched closely and any evidence of constipation must be religiously guarded against. With free action of the bowels, troubles at calving becomes remote. To this end, salt should be fed daily in the grain ration and for a week before calving, a small handful of of salt should be given daily. Managed in this way, difficulties at calving will not occur. In almost every case, aside from cold or exposure, retention of the placenta is caused by constitutional weakness and lack of nourishment. It is my experience that cows which have been well nourished and the bowels in free condition, are not troubled with retention of the placenta. On the other hand this trouble is mostly observed in cows that have been badly nourished. At calving time the grain ration must be reduced fully one-half for a week, and gradually increased, when the milk flows freely to the normal quantity.

There is no grain food that pays larger profits in dollars and cents than the grain that is feed during the month immediately preceding parturition, when fed intelligently; and there is no part of the cow's anatomy that will bear closer watching at this time, than the action of the bowels. Oil meal would be a fine feed to form part of the ration at this time, but it is considered dangerous. However, as there are some cows which are naturally sluggish in bowel action, to these some oil meal should probably be fed, if at hand, otherwise, with such cows, a dose of Epsom salts a week before calving may be necessary. In general this, however, will not be necessary, if common salt is fed freely.

About how much grain food should a cow be fed when a full flow of milk is being given? The authorities on feeding are daily changing the opinion on this important question. The results of the Wisconsin experiments, as per last report, are too vivid to be overlooked. Here it was found that 1.80 pounds protein was fully equal to the so called standard, and as protein is the ingredient supplied largely by the concentrates, it is plain that lots of high priced protein has been wasted in all these years. Prof. Haecker it seems was able to get three hundred to four hundred pounds of butter from a daily feeding of two pounds digestible protein, and Prof. Dean gets three hundred pounds butter by feeding only eight lbs. of concentrates composed of grain and bran only, no high protein content by-product, and declares that eight pounds of grain is sufficient for one pound butter fat—eight pounds grain and bran is sufficient for one pound butter fat, mind you.

Prof. Haecker, however, has put the matter quite plain, when he says: "feed .7 pounds protein for maintenance, then add 1.1 pounds protein for each pound butter fat produced. This is a simple key to the problem. If your cow gives one pound butter fat per day, then feed 1.8 pounds protein. If, on the other hand, she elaborates but one-half pound butter fat per day, then feed but 1.25, or one and one-quarter pounds protein per day, that is presupposing that the cow is fed to her capacity.

I, for one, am very glad that these most important disclosures have been made and amply verified, for it gives added hope to the ordinary dairyman, as I have sometimes asserted, who primarily from reading and studying the costly rations with the high protein content, which were thought absolutely necessary to feed the cow before such yields, as 250 to 350 lbs. butter could be expected, and which he could never afford to feed himself. Now the fact is made plain, that give then right dairy animal, the costly protein may be cut down by almost three quarters of a pound, and yet equal results may fairly be expected. I repeat, this announcement is bound to greatly stimulate dairying, and the problem of feeding will now partly give way to the problem of breeding. Dairy papers and dairy writers can now best give increased attention to the breeding side of the dairy cow—a phase of the question hitherto considered of secondary importance. J. A. M.

Hermanville, P. E. I.

A New York Herd Report.

ED. HOARD'S DAIRYMAN:—Being a constant reader of your valuable paper for the last four years and being very much interested in all that it contains I thought I would send you a report of my little herd of four cows. No. 1, 7 years old; No. 2, 5 years old; No. 3, 3 years old and No. 4, 7 years old. No's 2 and 3 are out of No. 1; No. 4 is a stranger; No. 3 came in the 27th of June 1902, first calf; she was about 30 months old when she came in, from May 1st, 1902, until April 30th, 1903; from those four cows I sent to the creamery:

Pounds of milk	25903
Average test	4.183½
Total butter	1158 lbs.
Money received	$241.45
Skim milk, 25 cts. per 100 lbs.	$59.75
4 calves, $3 each	$12.00
Total	$313.20
Cost of keeping	$157.04
Net Gain	$156.16

Now I bought all the grain my cows eat and I fed them grain every day except about two weeks before they come in so I know just what the grain cost me.

I have estimated two tons of hay for each cow and $5 00, each, for pasturage; that makes cost of keeping each cow, $39 26; the income was $78.30, which leaves a net gain of $39.04 over cost of keeping each cow. No. 1 freshened Feb. 8 and now after milking 105 days is giving from 40 to 42 lbs. a day. No. 2 milks from 35 to 38 lbs.; she freshened April 11th. No. 3 freshened June 27 1902, first calf, and is now milking from 18 to 22 lbs.; coming in again in Sept. No. 4 freshened April 7, not doing very well, off her feed for the past four or five days; will milk about 30 to 35 lbs. when she gets onto her feed.

What I want to get at is to show what HOARD'S DAIRYMAN will do for a man that don't know it all.

On June 7, 1900, I began to take my milk to the creamery from three of the same cows I have now, No's. 1, 2 and 4, and from June 7th until Aug 30th, they brought me $27.73. The next year they were even worse, didn't go to the creamery at all but on December 18, 1901, cow No. 1 freshened and I thought I would see if book farming didn't pay. I had been told a good many times when I had asked some of my neighbors to subscribe for the DAIRYMAN that book farming didn't pay. Well from Dec. 18, 1001, until April 30, 1902, from one cow, that is all we milked through the winter, we made and sold besides what we used in a family of 5, 116¾ lbs. of butter for $28.70. Then started to the creamery May 1st, 1902 and expect to do better another year than I did last, if we get any rain soon; pasture is all burning up and hay will be a failure.

I have no silo yet but I am in hopes to have one before long. Those cows of mine are like the German's cow, just barnyard cows, but I am breeding them to a thoroughbred Holstein bull. Wishing the DAIRYMAN a prosperous future. I remain. JAMES. G. MCINERNEY.

Buskirks Bridge, N. Y.

The Dairy Industry Prospers.

ED. HOARD'S DAIRYMAN:—There seems to be an unusually large demand for butter makers and cheese makers this year. Nearly all the cheese factories in Wisconsin are now in operation, but up to the first of May we received requests for cheese makers in nearly every mail. Our supply was exhausted early in the season and I think we must have had at least ten applications for every dairy student we could recommend.

The supply of butter makers now seems to be running short and I have before me five creamery applications which I cannot fill and have just received a telegram asking me to send a butter maker on the next train. A former dairy student also writes that his factory is receiving 16,000 pounds of milk daily and that he is paid $1,000 this year to run the creamery.

Another letter just received reads as follows:

"The man that you recommended to us a little over a year ago for a butter maker has given us good satisfaction in every respect. He is a first-class butter maker, honest, temperate and everything that we could ask for. The patronage has doubled since he came to us, but he is now going into business for himself and I write to ask if you can recommend another man equally as good to us."

In addition to these positions open for practical butter makers, there is also an unusual demand for educated instructors in dairy work. We have received within a short time applications for dairy instructors to fill five college positions, paying from eight hundred to fifteen hundred dollars per year.

Surely these are indications of prosperity in the dairy industries in Wisconsin.

If any of our former dairy students are unemployed and read this article, I hope they will write me at once, I keep informed in regard to a great many of them but some fail to write and I lose track of them.

We have recently recommended the granting of certificates to twenty-one students who have completed the necessary requirements for receiving these certificates during the past year. It is claimed that there are about 2,800 creameries and cheese factories in the state of Wisconsin. We have had 1,406 students in the Wisconsin Dairy School since 1890, and 240 of these have obtained certificates.

The milk supply at the dairy school is now 17,000 pounds per day. Some of the milk has a very strong grassy flavor and we are able to notice the effect of pasteurization on butter made from such milk. We find that it is very satisfactory, the pasteurized cream butter being decidedly superior to that made without pasteurizing. Some of our butter is now being placed in cold storage, but most of the products manufactured at the school, are sold in Madison.

Ten summer dairy students are improving the opportunity which our equipment and milk supply at the present time gives them for obtaining a thorough practical knowledge of dairying in its various branches. E. H. FARRINGTON.

SNAP, PUSH AND GO

Is What One Should Get from Food.

A young St. Louis lady learned a food lesson she won't forget. She says: "I suffered from indigestion for nearly 10 years and although I tried all kinds of foods for breakfast I could not eat any of them until one day I discovered Grape-Nuts and now I wonder how I ever did without it.

"I am a stenographer in a business office and need all the energy possible, but I formerly spent the greater part of every morning wishing I had gone without breakfast for I was continually reminded of it by the uncomfortable distressed state of my stomach. How much ability I lost through this I could not tell you but now all is different for I eat some fruit and a saucer of Grape-Nuts and work hard all the morning and never think about my stomach until lunch time comes.

"I feel the good effects of Grape-Nuts in a sharpened brain, better memory and increased thinking capacity. The only difficulty I have about it is that I never want to limit myself to the required amount for I love it so." Name given by Postum Co., Battle Creek, Mich.

There is a reason why Grape-Nuts sharpens the brain.

It's fun to make new and delicious desserts by the recipe book found in each package of Grape-Nuts.

It's Just This Way:

You can go on losing money on your milch cows if you like, or you can stop wastes, save half the labor and double your profits, by using an

WILL IT PAY YOU TO TAKE HOARD'S DAIRYMAN?

W. H. Jenkins took a census in 1901 of 50 farmers who were patrons of the creamery in Montrose, Pa. Twenty-five of themread dairy papers; twenty-five did not. The twenty-five who did read dairy papers averaged $50.23 per cow for the year. The twenty-five who did not read averaged $32.95. Here is a difference of $17.28 per cow. Did it pay the twenty-five to read? Did it pay the other twenty-five not to read? That's not all. Those who did read averaged a profit over cost of food of $15.06 per cow. Those who did not read averaged a profit of 66 cents. Is not that dairy farmer standing greatly in his own ight who will not pay 2 cents a week for Hoard's Dairyman? These are hard facts worth thinking over.

Prof. Massey, editor of the *Practical Farmer*, in an editorial entitled "What Will You Read This Winter?" says:

"The farmer whose specialty is dairying needs to read all that has been written by experts on his specialty, if he is to keep up with the wonderful advance that has been made in dairying in recent years."

The intelligent, successful dairymen believe that doctrine, and they practice it too. But the great mass of dairy farmers, the men who "don't know where they are at," the men who keep cows that eat their heads off every year, and they don't know it, these men don't believe a word of what Prof. Massey says. And because they so disbelieve they are sorely punished, getting every dollar that they earn at the very hardest.

An old German dairyman, who makes about double the money out of his cows than any patron in the same creamery does, once said to us: "Some Yankee mens peen awful smart, but an old cow can fool 'em effery time."

In handling cream for churning, John Michels, Instructor in Dairying in the Michigan Agricultural College, says he has found it best to ripen the cream first then cool it, rather than the usual way of cooling first and ripen afterward. Private buttermakers as well as the creamery operator can easily try this, and it may be the change will bring very desirable results.

Miss Laura Rose of the Ontario Agricultural College, has been traveling in Nova Scotia on an educational trip with her traveling dairy. She has spoken to over 6,000 people at 171 meetings; has made nearly 1,000 pounds of butter, and 640 tests of milk with the Babcock. All this before her audiences. She found that the Nova Scotia farmers were about the same as those in other parts of Canada and the United States; that if they learned much of anything the teacher must go to them. Miss Rose has done a work and under a method that should receive the attention of authorities in other states.

Where men are ignorant of the true principles of their business they are invariably suffering by it. But the thing is to get them to see their own ignorance, and "turn from the error of their ways." The editor of the *Southern Farm Gazette* took a trip among the milk dairymen in several of the towns about him. This is what he says:

"There is lamentable ignorance abroad in the land with regard to feeding milk cows. We find scores of town men who are feeding from ½ gallon to a gallon of cotton seed meal at a feed. A quart at a feed is ample for an average cow giving a good flow of milk. Much more than this will not increase the flow of milk, but will make her fat, often destroying her usefulness from being over fat. As much as a gallon at a feed, which means 16 pounds a day, is quite expensive, and probably most of it passes off undigested. About 1 quart of cotton seed meal, and 2 to 3 quarts of wheat bran, with hulls, coarse grazing or other rough food, make an excellent feed and reasonably cheap."

There are thousands of such dairymen all over the land, doing business every day without right knowledge or understanding, but no one can make them see it or believe it.

IMPRISONED IN THE PAST.

In his address before the Wisconsin State Teacher's Association, President Karl Mathie made use of a sentence which means a great deal. Speaking of the teacher he, said:

"The teacher easily becomes imprisoned in yesterday's knowledge, in yesterday's methods. He is too prone to look back for details instead of looking about him for present inspiration."

Mr. Mathie's apt characterization hits the case, not only of certain teachers, but it applies exactly to the life of thousands of dairy farmers. They are "imprisoned in yesterday's knowledge," and securely locked up in yesterday's method's. They forget the operation of that great law, "circumstances alter cases;" that every new day brings with it new circumstances, new problems, new changes, new conditions.

There is no business on earth that involves such an infinite variety of circumstances, contingencies and changes as animal farming. Why? Because it is dealing with the most changeable, varied forces of all the earth, that of life—animal and vegetable life.

A few principles are fixed; they belong to yesterday and today. But out of them comes the almost infinite play of an infinite variety. No two blades of grass are alike; no two animals of the same species are alike, or can be treated alike successfully; no two farms are alike, or can be farmed alike. With all this tremendous variety, the business of dealing with these ever varying forces is turned over to a class of men, in a great many instances, who do not read, do not think, do not travel, do not study, or do anything but imprison themselves in the knowledge and methods of yesterday, which half of the time, do not fit the exigencies of the case any more than does a "square pin in a round hole."

Every effort to wrench these men out of their misfit conditions, to get them to see how little they know of the forces they are dealing with, how much they need to awaken their mind and thought, for their own sake, is met with skepticism and unwillingness to believe in anything but the worn-out impracticable knowledge and methods of "yesterday."

Ask them if they are satisfied with their present state of knowledge and the use of their present methods, and they will answer "yes". Ask them if their stock of knowledge and their methods are bringing them profit, and they will sadly say, "no."

But nevertheless they are satisfied that the fault is not with their knowledge or methods. What a strange paradox these men present.

AS A SUCCESSFUL DAIRYMAN SEES IT.

There is a broad, well defined issue constantly standing between the dairymen who think and act with HOARD'S DAIRYMAN, and the great mass of dairy farmers who adhere to worn out methods, which bring them but little profit and often direct loss. Years ago the DAIRYMAN set out on this crusade. It saw clearly that before there could be any marked success or profit in the business there must be a change, a reorganization of ideas among the dairy farmers of the land. It saw also, there must be injected into this work, more and better thought, sounder knowledge, a more willing spirit to learn, a greater willingness to see what is wrong in theory as well as practice. Our standard was different from the great mass of dairymen. It was not our own notion, so much as it was the methods, the results, the profits, and the avoiding of losses as shown by the wisest and best dairymen of the land. These men had pioneered the way. They had shown it was the best way. They had demonstrated that the magic spirit that brought such good results was not blind money or capital, but rather bright-eyed intelligence, more brains, more faith in brains and less in stupid tradition. All over the land is a host of men who are keeping cows according to tradition; doing the thing from morning till night as grandfather did it, and for no other reason. Their profits are painfully small, but that don't move them. They console themselves by saying: "I guess I am doing as well as my neighbors." When we make a thorough investigation, as in the Cow Census work, the poor work, low profits and poor understanding of these men and their neighbors, are shown up in a clear light. So we say that between HOARD'S DAIRYMAN and this great majority of half-paid, half-thinking, non-reading cow keepers, there is a broad issue. Mr. J. F. Schlappi, the man who had charge of the feeding of the cows in the Breed Test at the Pan-American, last year, in writing us under date of May 25th, says:

"Years ago, in Northern New York, where I still have my dairy farm, the farmers used to call me a "crank". But later on, when during the hard years I managed to pay for the farm, the tables turned. Oh! This dairy business, I wish I could enthuse every cow keeper to see and act as the real truth is. For instance, I doubt if there are over 1,000 dairymen in this country today, who fully realize the value to the dairy farmer of alfalfa. I repeat what I wrote you some time ago, that this plant cannot be talked about too much. The more it is talked about, looked at, and got acquainted with, the more valuable it seems to get. I said before the Kansas Dairymen's meeting that the butter production east of the Mississippi river, would come to be an insignificant factor within the next 25 years; that the enormous increase in the consumption of milk would bring this about. The statement in the DAIRYMAN on page 342, bears witness of my not being too visionary."

Mr. Schlappi used thought, good dairy sense, and made himself intelligent. He paid for his farm. Hundreds of other men in Northern New York ran every year deeper in debt. They consoled themselves by calling Mr. Schlappi and HOARD'S DAIRYMAN, "cranks." They are at it yet. A stern chase after foolishness is a long chase, and it will always find plenty of chasers. What consolation it must be to these men, to be what they are. How they do prove that there is no cash value in better thought, better ideas, better understanding.

MAKING VEALS ON SKIM MILK.

One of the important by-products of the dairy farm is the skim milk, if the farmer will but study how to use it in the most economical manner. A large proportion of the calves among creamery patrons are sold when a few days old, for a trifling sum. Yet these men have all the means at hand to make a handsome profit out of the skim milk by feeding it to the male calves, and turning them at 5 to 6 weeks of age for veals.

A Massachusetts farmer describes how he does it in a recent communication to the *American Cultivator*. He says:

It does not seem to be generally known that first-class veals can be made on a basis of sweet skim milk. Yet a great many calves reach the market and bring high prices, although never fed a quart of whole milk after the first day or two of their lives. These calves, if properly grown, look as well as any. Butchers say there is not so much internal fat, and the calf is therefore not quite so heavy as the whole milk calf, but he brings the same price, at least in the markets of towns and small cities. The writer last summer sold calves which brought the going price in the local market, 6½ cents live weight, and averaged about $9 50 value at five weeks, but were fed practically nothing but sweet skimmed or separated milk, to which was added a handful of fine wheat flour for each gallon. It was reckoned that the skim milk so used, brought about two cents per quart. The flour cost about thirty cents per calf. Flour, being fine and starchy, is mixed easily with milk and is much better than anything else. Other farmers in the vicinity use extra fine ground corn meal, fine feed, oat meal, etc., but with less satisfaction. The main points are to have the milk sweet and plenty of it at fairly regular hours, and to give the calf nearly, but not quite, all he will drink. One feed a day from the cow during the last week is a help, but is not usually necessary. It is important to have plenty of dry bedding to save warmth, as a skim-fed calf has no fat to waste keeping his body warm. Pails should be rinsed after every feed to avoid disease.

That point about dry bedding is very important. It is much harder to provide for this with male calves, but it will pay richly to see that it is done. In all of our calf raising we have considered this point of keeping the little animal dry and clean as one of the highest importance.

GOOD REASONING ABOUT COWS.

A large proportion of the farmers who keep cows, make but starvation wages at the business. That fact can be proved by taking a "Cow Census" at any creamery. The reason for this state of affairs is that these men are poor reasoners. They have but little real sound cow knowledge. The money they get out of the business, proves that. When one man, a next neighbor, gets $2.00 for every dollar spent in feed, and the other gets only 60, 70, 80 and may be 100 cents, that tells the story of brains. There can be no denying it. It is not luck; it is brains. What makes these poor dairymen the men they are? They have a contempt for good sound knowledge; that is what's the matter. There stands the same creamery for one man as for another. One uses his brains; the other does not. It sounds hard to say it, but it is Heaven's own truth, and it is time the truth was told. A lack of sound dairy knowledge produces a lack of sound dairy reasoning and that produces the wretched, poor ideas and methods, and results we see on these dairy farms, where the owners "can't learn anything from what they read."

C. E. Chapman of New York, is a good reasoner on cows, but he did not make himself so by despising the experience of others. Here is a sample of some of his reasoning on cows, in the *Ohio Farmer*, he says:

Every wide-awake dairyman should raise his own cows. Some men buy all their cows, claiming that it is cheaper than to raise them. A visit to a creamery recently, where this practice prevails, reveals the fact, that the average butter production was not over 200 pounds. One poor fellow had but 130 lbs. I did find

one man that had 300 lbs., but he did not buy his stock.

Where do the cows that are for sale come from? In some adjoining county a speculator has gone among the farmers and bought everything for sale. Does any one think a farmer would sell his best cows at the price usually paid for "pickups?" The results at this creamery show they do not. Every fall a few carloads of just such unprofitable cows are shipped out to just such places as the above. We can not make any money out of them, and sell for what we can get. I do not believe any one but an expert judge can buy the cows and keep a good average herd.

A man who keeps 60 cows and buys them all told me that he drew as many blanks one way as the other, and I did not doubt it, for as milk was the mainstay, the calves did not get enough to make a large growth.

This leads HOARD'S DAIRYMAN to say that a man who raises good cows must be a good calf and heifer raiser. There are too few men who are really good calf raisers. What is the matter with them? They are not good reasoners on calf life. They will not study. They are willing to work at coarse work, but they call fine work like calf raising, "puttering." So they say, "I can't putter with a calf." Nine out of ten of the heifers come up without a bit of special thinking back of them, as to whether they should have good dairy blood in them or not.

The owner couldn't afford to "putter" enough to raise them well after they were born. Then he can't afford to "putter" enough to do anything special to develop them as cows in the first two years of their milking, and here we are all the time, with not one cow in a hundred that will make 275 to 300 lbs. of butter a year. Mr. Chapman further says:

How many know what a good cow is? Three or four thousand pounds is believed, by many, to be a good fair average, and they raise the eyebrows when told of 10,000-lb. cows. It all depends on one's standard, which is made by the man's environment and education. In some sections the land is poor and hard to work; there is little plow land and the growing of ensilage, soiling crops and roots unknown. In such sections a large yield is almost unknown. In others, as in Delaware Co., N. Y., the land is cheap and fertile, producing good summer pasture. The farmers keep all the stock they can, plowing but little, and wintering the stock on purchased grain, often carrying a cow per acre for the cultivated land. The large amount of purchased grain makes an abundant manure pile and the small fields get richer and richer. The milk yield in such cases is large and growing larger. Here a cow is simply a machine to utilize cheap grasses in summer and purchased grain in winter for milk production, and unless the cow will produce $60 worth of milk or butter she is not considered a good one.

At one creamery 200 lbs. of butter at 20 cents, gave an income of $40, average. Inquiry showed that it took five acres of land to keep a cow. The cost of the food alone would be $35 per year, which leaves an income of only a dollar per acre for all other expenses, losses and interest, counting the manure equal to the labor. These are not good cows, but "robber" cows.

The actual value of milk is ascertained by finding the amount of butter fat in it, in practice as well as theory. They pay $1.10 for a hundred pounds of milk and sell it back for 5 or 10 cents after the butter is taken out, if they can get it, and I have known of it being run into the creek until the health authorities objected, when they hired men to draw it out and dump it. The butter fat is what we are after. I purchased a fine cow once that gave 50 lbs. and over per day, but found at the end of the week that we had no more butter than before. By using a Babcock tester I found that she gave milk that did not test more than 2 per cent, and I do not think all of that would gather in the churn. One large dairy at the milk station would not test 3 per cent, much to the owner's astonishment.

No man can afford to keep such cows, or to go on without weighing and testing the milk from each cow. When I purchased my tester I made a table, placing the cows in order of their value for butter production. After the test was completed I found the supposed No 1 cow was actually No. 5, and a cow which I had offered for half price was giving the largest profit. I have ceased depending on my "natural shrewdness" in picking profitmakers, and use something more accurate. "Weighed in the balance and found wanting" applies to both man and cow, often times. If we are struggling along with a lot of cows as poor as we are, the best thing to do is to be honest with ourselves, and put both "on record" and then look at it, even if ashamed, until we get so sick of it that we make a change. Records are valuable because they make us miserable if poor and stimulate us to do better if good. Without them, we never think of it.

Take what Mr. Chapman says and go out and read it to one of those farmers who have poor cows and are contented to keep them, and are afraid to know whether they were poor or not. Ask that farmer these questions:

"What do you think of what Mr. Chapman says? Is he right? Are you doing any thing to put your self or your cows on a better profit making scale?

Are you doing anything with your own mind and judgment? Do you really know any more about your cows or the principles of your business this year, than you did last year? Are you not running along in the same old rut of "don't know?"

We will guarantee better cows all over the land in three years time if the farmers who own the cows and who breed and raise them, will honestly ask themselves the above questions, once a week for a year.

Wisconsin Itinery of the German Agriculturists, now Traveling in This Country, June 12-15.

Early last month a party of forty-six German Agriculturists arrived in New York for the purpose of studying American agriculture. They were taken in charge by Mr. Schulte, a representative of the U. S. Department of Agriculture, Washington, who accompanies the party on its trip across the Continent and back again, making a journey covering 10,400 miles in all. They travel in special cars, visiting en route stock farms, agricultural colleges and other objects of agricultural interest. The accompanying list gives the membership.

The party will reach Madison on Saturday morning, June 13th. The plan of entertainment contemplates a morning drive over the park system laid out by the Madison Park and Pleasure Drive Association, returning to the University farm to inspect its various departments, reaching the Park Hotel for dinner at one o'clock. The afternoon program includes a visit to several University buildings and a boat ride on Fourth Lake. They will leave Madison for Milwaukee in the evening, where they will spend Sunday, returning to Lake Mills and Ft. Atkinson, Monday. At Lake Mills they will visit the Holstein herds of F. B. and E. J. Fargo and Wm. Everson and The Fargo Dairy Supply Factory. At Fort Atkinson they will inspect the HOARD CREAMERIES, the Cornish, Curtis & Green Dairy Supply Factory and the dairy farm of W. D. Hoard. From the latter point they go on to the Dunham Horse Farm, Wayne, Ill. A number of Wisconsin citizens interested in agriculture will be invited to meet these distinguished guests and to assist in their entertainment.

PERSONEL OF THE PARTY.

Dr. Victor Ritter von Bauer, Bruenn, Austria.
Maximilian Beuther, Posen—owner of feudal estates
F. Biermann, Sanitz, Mecklenburg—owner of feudal estates.
Ulrich Bohm, Kluetzow, Pomorania—agriculturist.
F. R. Brettreich, Munich, Bavaria—government official.
Conrad Eberhardt, Speyer on the Rhine.
Dr. Alfred Dietrich, Coblenz—government official.
H. Eyssenhardt, Rangsdorf, Brandenburg—owner of feudal estates.
R. Frederick Ferber, Gera—agriculturist.
Ottomar Fouerstein, Parchwitz, Silesia—agriculturist.
Dr. F. H. Flecken, Cologne.
Erich von Fluegge, Speck, Pomerania—government official.
Th. Fuehling, Frechen Rhenish Prussia—director of large estates.
A. Furhmann, Berlin—agricultural student.
Kurt Gaebler, Sorau, Brandenburg—agriculturist.
Armand Gain, Peske, West Prussia.
Henry Gildemeister, Berlin—agriculturist.
Bernard Gontard, Leipsic—agriculturist,
Chas. Hanisch, Breslau—dirccter of estates.
H. Kloevekorn, Uderwangen—owner of estates.
Victor V. Laffert, Brahlstorf, Mecklenburg—Lieutenant of the Reserve.
Hans Lampe, Leipsic—agriculturist.
Dr. Eugene Count Ledebur, Lobositz, Bohemia.
E. Lemcke, Hoppenrade, Mecklenburg, Schwerin—agriculturist.
Dr. Felix Lindemann Dresden—agriculturist.
P. Moeller, Schlieffenberg, Mecklenburg—owner of feudal estates.
Ferdinand von Prachter, Munich, Bavaria—government official.
C. Rechholtz, Doelitz, Pomerania—owner of feudal estates.
Walter Richter, Tapiau, East Prussia—agricultural inspector.
Fred Rueffer, Heidelberg—student.
Bernard Sachse, Weizig, Saxony—owner of feudal estates.
Jacob Schloesser, Koeln—Ehrenfeld—student.
E. Schneppat, Moulienen, East Prussia—owner of feudal estates.
Count von Schnurbein, Rain, Bavaria.
Ernst Simons, Elberfeld—agriculturist.
Chas. Skene, Jr., Breslau—agriculturist.
Count Schenk von Stauffenberg, Risstissen, Wuerttemburg.
Fred Staakmann, Leipsic.
Anton Triep, Elberfeld—agriculturist.
Professor Vielhauer, Mosbach Baden—teacher of agriculture.
A. Wadsack, Tennstaedt, Prov. of Saxony—owner of feudal estates.
Mr. Wagner Neudietendorf—agriculturist.
Martin Weissenborn, Fiddichow, Pomerania—agriculturist.
W. Wien, Lalendorf, Mecklenburg—agriculturist.
Dr. Martin Willner, Berlin—agriculturist.
O. Winkler, Lockwitz, Saxony—owner of estates.

The Value of a Good Man.

ED. HOARD'S DAIRYMAN:—I heartily endorse what L. O. Jackson says in writing to the *Jersey Bulletin* of his experience with hired help and the dairy cow. I have learned by experience that a good, quiet, neat and thorough milker can easily earn his employer from ten to fifteen dollars more every month, than the other fellow who takes no pride in his work and can milk the same number of cows from one-half to one hour quicker in the evening than he can in the morning. This one thing is proof enough for me that he is not the man that we want in our herd at any price.

I have in mind a herd that was being milked by a man like the first mentioned, who was turned off for a very small reason, and the other man that took his place was like the latter mentioned. The milk was weighed and put down on the milk sheet. The number of cows which were milked were thirteen. Within two days after the second man went to work the cows were giving two and one-half pounds less milk than when the other man was milking them, the cows being fed and cared for by the same man in both cases.

The way I figure this, there was about 33 pounds less milk drawn from the 13 cows each day, which would no doubt test from 6 to 8 per cent, as it would be the stripping that was left in the udder. This would be about two pounds of butter, which would be worth 40 cents. This would amount to $12 a month, to say nothing about the harm that he was doing the cows by not stripping them clean. This kind of milking carried on very long would put the cows where it would take a good milker a long time to get them back to where the first man had them. Perhaps some of them would never come up again.

So you see you can hardly measure the difference in value between a good man and a poor one in a dairy herd. I would say, if a dairyman has a man that he knows to be a good feeder and a thorough milker, to study the matter well before he makes a change and not change for a few dollars on the month, and cause the tried man to go and accept the stranger. This is one of the problems that is staring the dairymen of this country now in the face, to get good, competent men to stay with their cows. The farmers should keep better cows, and then they can afford to pay better wages to better men.

It is a hard matter to keep a good herdsman with a lot of worthless cows, and it is a harder job to maintain a good herd of cows with a worthless feeder and milker. Good men and good cows should go together, and poor men and cows should be discarded altogether.

Knapp, Wis. R. H. P.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

A Silo Query.

Enclosed find five cents stamps. Please send me a sample copy of your record sheet for ten cows; and please answer the following question:

In building a stave silo with the intention of bricking it up on the inside in the future, what distance would you advise to place sill of silo away from the inside edge of silo foundation. Do you thing 4 inches would be sufficient? W. P. K.
Weyauwega, Wis.

Four inches is quite sufficient if brick are laid up on edges, otherwise five to six inches would be none too much.

Mold in Cheese Cellar.

Am keeping Holstein cows and making cheese, buying some milk from my neighbors. Am using the cellar for curing room, but am troubled with mold. Is there any way to prevent cheese from molding. L. C.
Garrison, Ia.

If the cellar is at all damp the cheese is very apt to mold and this can only be prevented by ventilation. Even then there is liability of mold, if the cellar has, as is probable, become infected with the mold spores, and a thorough cleansing and whitewashing is necessary.

Shredder or Cutter for Silage?

What has been the experience of our readers in the use of shredders for filling silos? This is a question frequently asked us and our information on the subject is too limited to warrant reply.

Sterilizing Whey.

Could you give us any information in regard to sterilizing whey, at what temperature, etc.
Seeley Creek, N. Y. W. G. C.

Whey is usually sterilized by running exhaust steam into the whey tank till the proper temperature is obtained. This should be in the neighborhood of 155° F., but should not go above 160° F. as the albumen of the whey coagulates at 160° F. and will settle to the bottom of the whey tank, making it difficult to distribute to the patrons, as the albumen is the most valuable part of the whey.

Summer Sowing of Alfalfa.

Is June 1st too late to plant alfalfa? We are going to try a small amount, and propose to sow it in the same field with corn, but owing to the extremely dry weather in this section, have been unable to plow. This is sandy loam, with clay sub-soil and is about 15 feet or 20 feet above water level. C. BROS.
Chester Co., Pa.

We have much to learn about sowing alfalfa, especially in a country that has all kinds of climate, from sub-tropical to semi-polar, but it may be laid down as a rule, that summer sowing of alfalfa is possible only where the months of July, August and September can be depended on for sufficient rain to allow the young alfalfa plants to keep up a continuous growth. The young plant is very tender and must make sufficient growth, at least in the middle west, to form its own protecting mulch. This it will not do in this locality, and accordingly it is sown in the spring. Our correspondent knows more about the summer rainfall in his state than we do, and can thus judge of the probability of the summer growth of the young plant being sufficient to go through the winter with sufficient protection.

A Lazy Bull--Silos.

Have bull nearly two years old "pure bred," looks to be in fine condition, that is very slow to serve. Kept in the barn except when turned out in yard for exercise; has a good stall and fed clover hay only.

I am going to put up a silo and don't know the first thing about it, for twenty five head. I ask you to give all the pointers you can. W. H.
N.Y.

Feed less carbohydrates and more protein; the bull is likely too fat, more exercise will be beneficial.

We have been over the silo question so fully in recent issues that it is impracticable to recur to the question from the beginning, at this time.

Keeping Cream Sweet.

Please give the best method for keeping cream sweet for two days for city retail trade. A READER.
Fort Wayne, Ind.

If the dealer has control over the production of his cream there is no difficulty in keeping it sweet for several days if the cows, stables and milk utensils are kept in a clean and sanitary condition, as has been explained so often in the DAIRYMAN (See page 210 of the current volume.) If on the other hand the dealer only receives milk and has no control over its production, pasteurization is the easiest way out of the difficulty.

Comments and Queries from Robinswood Farm.

Relating to the Special Type of Cow the Dairy Farmer Ought to Demand From the Breeder, and Strive to Create at Home.

ED. HOARD'S DAIRYMAN:—In my last communication I referred to my belief that before breeders generally can be expected to give to their patrons the type of cow that will most nearly approach to the economic ideal, the demand for such a type must be made from without by those who are going to use the blood. The dairy farmer ought to know just what kind of a cow is best fitted to his needs, but unfortunately only a small proportion of farmers have any near approach to such a perception, and in the general state of our knowledge at the present time, no one can say definitely what the ideal should be. Some of us though have some pretty strong opinions as to the matter. When a clearly set and generally accepted ideal is mapped out, progress will be reasonably rapid in supplying the ideal.

It may be of help to some if I now place on record my own conclusions as to this matter, and incidentally thereby indicate the type of cow we are trying to create at Robinswood Farm. The subject should be considered from the structural and functional points of view, as well as with relation to the pedigrees or inherited tendencies of the animals under study.

First, let me say again that I think that every dairyman should differentiate his selection of type, not only between the special-purpose dairy type and the dual-purpose beef and dairy type, but also he should go so far as to select within the dairy type, representatives that are either of a special-purpose butter type, or of a special-purpose milk type, according to the requirements of his practice, for I presume that every progressive dairyman in this day understands that to succeed best, he has got to adopt some one of the specialties into which dairying is divided, and must pursue that specialty with the fullest ardor. I think that we are forced to an acceptance of the proposition that a highly evolved butter type of cow can make butter fat more cheaply through the use of a broader ration, than can a type of cow that is more especially a milk cow solely. In the latter case one needs a cow whose ability to digest much protein is strong, and to whom it will be profitable to feed a more narrow ration than to the other cow. I think that we will find that as intelligence increases among milk consumers, they will not demand a milk very rich in butter fat for direct consumption. They will find out that the greatest nutritive value of milk is in the nitrogenous and earthy salt elements, and that only a reasonable amount of accompanying fat in the milk is desirable, and that that fat should be in the form of small globules.

If, then, it is the farmers purpose to produce butter fat, it is certainly wise for him to select blood from a breed in which the breed tendency is to produce large percentages of fat, for the chances are largely in favor of the progeny of such blood producing a certain amount of butter fat at a lesser cost for food than if he selects a breed in which to create the same amount of fat, for a larger proportion of protein has to be eaten and digested. On the other hand, if milk of a medium or low degree of richness in quality as to fats is wanted, it follows that a breed ought to be selected in which the breed tendency is to have a highly evolved power to digest much protein; for other things being equal, the more protein digested, the more milk will be produced, so far as quantity alone is considered.

There can be no question as to not being able to let up on a narrow ration if large quantities of milk are wanted, and if the cows used are of high power as protein digesters. It would be unwise for the butter dairyman to select for the betterment of his herd blood, if the example which he selects would happen, as an individual or as a member of a family, to have a large percentage of fat, but that did not have also the breed tendency to that kind of production; for the breed tendency would crop out in the posterity of the individual with more or less certainty. The principles of specialism should be carried out to the full in dairying.

With the present amount of knowledge on hand there does not seem to be any practical way of completely judging as to the real economic merit of any cow, and as to her merit as a breeder, except from her productive record, and from the records of her ancestry. In this day, when we have the Babcock test, there is no excuse for a breeder not being able to exhibit a record of the weekly product of any of his cows, both as to quantity and quality of milk. As to the ancestors of the cows now living, we must for the most part rely on the records of seven-day tests, because in the past there was only the churn test, a most inconvenient and expensive test for the regular recording of yields for extended periods, and therefore breeders seldom did more than to make a few short tests. Unfortunately, the custom led to the abuse of making such tests, forced tests, which are defective so far as establishing the true profitableness of the cow, and which bear insufficient evidence as to the year, in and out, productive power of the cow. The buyer of dairy blood should, therefore demand a full report of the product of the blood he is to use, especially a yearly report.

Just what the per centage of butter fat should be in the milk produced by a butter cow is not yet scientifically determined. Yet it is quite probable that from 4.5 to 5.0 will, on an average for the year, prove to be the ideal as an outcome of the best economic feeding conditions for long periods in most of the states of our Union. The amount of butter fat that should be produced each year by each 100 lbs. of mature cow is also as yet undetermined, but I think that about 40 lbs. will prove to be nearly right. For example, a mature cow weighing 600 lbs. ought to give about 240 lbs. of butter (15 per cent overrun), an 800-lb. cow should produce 320 lbs., and a 1,000-lb. cow ought to give well up to 400 lbs. as an ideal yield. A close determination as to this matter can only be arrived at after a very large number of comparisons of the records of various cows have been made and carefully studied. Here is work for our institutes. This is the kind of knowledge that is needed by the dairy farmer, and by the breeder as well.

I think that the buyer should be shy of very large yields with the first calf. Here is another point still to be determined officially and authoritatively. Then again, some think that a two-year-old heifer that will give ten lbs. of butter in her best week, if she had not been pushed too fast, could be relied on to give 18 lbs. in seven days, at maturity. Others would say that an increase of 50 per cent, or a total of 15 lbs. at maturity would be about right. It seems to me that a two-year-old heifer that has not been forced for early maturity by the feeding of too easily digested and too concentrated food, and if of a moderate size or under, if she gives 8 lbs. of butter (15 per cent overrun), at her flush, ought to be carried into the 14-lb. list after four or five years of right feeding and care. The pasture-utilizing dairyman at least, should as a rule, avoid a large cow for his purpose. Largeness of size in a cow is usually the result of late breeding, of very abundant

EXPERT TESTIMONY.

Coffee Tried and Found Guilty.

No one who has studied its effects on the human body can deny that coffee is a strong drug and liable to cause all kinds of ills, while Postum is a food drink and a powerful rebuilder that will correct the ills caused by coffee when used steadily in place of coffee.

An expert who has studied the subject says: "I have studied the value of foods and the manufacture of food products from personal investigation and wish to bear testimony to the wonderful qualities of Postum Cerial Coffee. I was an excessive coffee drinker, although I knew it to be a slow poison. First it affected my nerves and then my heart but when I once tried Postum I found it easy to give up the coffee, confirmed coffee fiend though I was.

"Postum satisfied my craving for coffee and since drinking Postum steadily in place of the coffee all my troubles have disappeared and I am again healthy and strong.

"I know that even where coffee is not taken to excess it has bad effects on the constitution in some form or other and I am convinced by my investigation that the only thing to do if health and happiness are of any value to one is to quit coffee and drink Postum." Name given by Postum Co., Battle Creek, Mich.

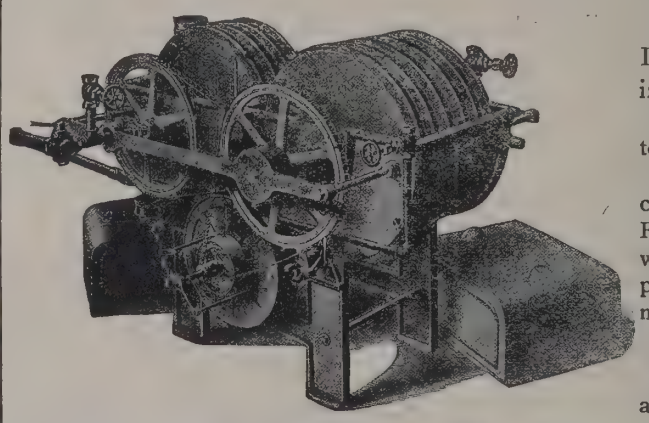
There are many reasons why the Improved

U. S. SEPARATOR IS THE ONE TO BUY

BELOW ARE A FEW OF THEM:

THE U. S.

Costs no more than inferior machines
Gets More Cream out of the Milk
Is less expensive to operate
Increases the quantity
Improves the quality
Will wear longer
Soon pays for itself
Has its gears enclosed
Bowl has few parts to wash
Has simple self-emptying Bowl
Has many other points of superiority
More fully described in our catalogues which are free for the asking, all making



The U. S. Separator the Standard Separator of the World

feeding of easily digested food, and infrequent breeding, and we seldom find a sufficient proportionate mammary development in these animals to secure the most profitable results. Hence the needed food of support is likely to be too great. That exceptions are found to this proposition is due to conditions apart from the matter of size, and they do not invalidate the rule as stated. Large cows incline to the dual-purpose type.

While over production of a large flow of a milk product very rich in total solids, especially of the nitrogenous and mineral elements in the breeding cow, is to be depreciated, such examples are comparatively rare in the distinctively butter type of cow. In most cases, the trouble is to find a type of cow in which the mammary development is profitably large in proportion to the general muscular and bony systems. As a rule, such desirable conditions are only to be found in small or moderate sized cows. It is the big little cow that has little tendency to the dual-purpose type, that is the profit maker.

Unfortunately, there is no distinct milk cow type that has not more or less of a tendency to the dual milk and beef form. The Holstein people make as one of their ideal requirements that a cow shall weigh over 1,000 lbs. at maturity. I am inclined to think that this is a mistake so far as economic milk production is concerned, and is an undesirable relic of the dual-purpose idea for which the breed has been bred in the past in her native habitat. Still we must admit that for level lands with bush pasturage, the large cow is not a bad machine to work with, especially as watered feeds make watered tissues. But whatever the weight of the cow, the dairyman should seek to get one with a relatively very large development of the abdominal organs and spinal column; and a relatively small development of the general muscular system. The other structural peculiarities of what I consider a good cow, have been so frequently described in this paper that I need make no repetition of them here.

Any type of cow that is defective in constitutional vigor, or that is lacking in a reasonable ruggedness of health, or that has not become reasonably well adjusted to the conditions which will environ her in her regular work, is not best suited to the economic needs of the dairyman.

A good cow must be given more protective care than the average scrub, because a larger proportion of her digested food goes to the udder than is the case with the scrub cow; but even the good cow must be subject to a considerable amount of trying climatic and atmospheric conditions in the farm practice of most sections in the regions of our country devoted to dairying. The blood of cows that have been coddled, both as to protection and as to feeding, with a view of securing very high tests, is not of as much practical use to the dairyman as is that which is grown cold, so to speak, and so treated as to acquire a full degree of constitutional vigor.

In order, therefore, that the buyer of dairy blood can come to an intelligent judgement as to the value of the blood he is to use, he ought, among others, to be informed as to the following points. 1st. The average weight of the strain under consideration at successive periods of life. 2d. The rate at which productiveness has been developed, i. e.: Whether early, large production has been sought or otherwise. 3d. The quantity of milk that has been produced in each week of life. 4th. The quality of the milk produced as determined by a weekly Babcock test. 5th. The quantity and quality of food that has been fed. 6th. The date of each calving. 7th. The nature of the progeny, both as to constitutional vigor and as to productiveness of progeny. 8th. The physical conditions of both dam and sire at various periods of their lives. 9th. Full pedigree or history of ancestry. 10th. Structural and functional defects.-(N. B. Every animal has some "out") 11th. Nature of the animal as to ease of milking, temperament, including docility, nervousness, etc. 13th. Record of attacks of sickness, abortions, etc. 14th. The climatic influences which have been exerted. 15th. Pasturing influences that have been customary. 16th. Amount of protective care given, especially as to length of time stabled. 17th. General care and management practiced. 18th. Demonstrated profitableness of type. 19th. Portraits of animal and relations at various periods of life. 20th. A personal inspection of the structural form, which of course should be of the dairy type and in distinct contrast from the dual-dairy and beef form.

A consideration of the above, leads to the conclusion that there are more things to think of in connection with cattle breeding than many persons would suppose, and that the up-to-date dairyman has got to be an intelligent individual with a special training, and besides good powers of judgement. There is certainly a field and opening in this profession for special ability. There is plenty of room for the exceptional man, but the requirements as to ability are without question very exacting; and there is little likelihood of advanced dairying being overdone at present. The right kind of man has got to have natural aptitude and has got to have special training from childhood up. My personal opinon is, that before many such dairymen are created, the state or nation has got to step in and establish preparatory schools, especially for the purpose of forming the grown man to meet home conditions and for keeping the right sort of individuals at home on the farm, by special education. The Agricultural College does not begin early enough; does not get enough of the right material to work with.

Silo Experience.

ED. HOARD'S DAIRYMAN:—I have been a reader of the DAIRYMAN for several years and have received much benefit from it, and have become very much interested in our German friend's talk on the silo, and like Mr. J. N. Meroney, wish to help convince dairymen of the great value of silage, as a dairy feed. While Mr. Meroney's silo is all right for Tennessee. (as I lived there five years and know the difference in the soil) it would be a failure in this part of Ohio; therefore for Ohio readers I will say if you want a ground or dug silo, you must wall or cement below the surface of the ground in this kind of soil.

My husband built our first silo three years ago and we think that we could not do without a silo at all now. We used wire hoops and built thirty feet high and thirteen feet in diameter; this was for ten cows through the winter.

We filled the first year with corn and cane, and like our good German, we had very good sourkrout. We put in a load about; and as we are not sourkrout Dutch (my husband being German, Irish and English, making somewhat more of a mix up than ever) therefore we did not want that, so we have filled with common field corn, the last two years and will continue to do so. We cut with corn harvester, when the ears are filled and beginning to turn brown and the grain well dented, cutting one-half inch.

For feeding or emptying the silo, we invented a plan of our own (English getting the praise for this invention) as follows: On each side of the doors, which are one above the other four feet apart, he spiked a two by four scantling, across these he nailed cleats making, a ladder from bottom to top. Then he made a chute large enough for a man to pass up and down the ladder. Then he throws the feed out of the doors and it falls straight to the feed room, in front of the cows, making it very little trouble to feed the cows.

We think that dairying pays. Six years ago we came from the South with nothing to buy a cow with and had to buy on time. Now we have machinery of all kinds, to farm with; a dairy of nine cows; a Sharpless separator and fully equipped for making butter. It is all paid for, and we know that we could not have done this without the help of the dairy. We bought a farm this spring and now we have to build another silo. We expect to build it with Georgian pine single ply, 15 feet in diameter and 30 feet high, hooping with wooden hoops. Are we making a mistake in our plans or not?

Lunda, Ohio. J. A.

Weight of Cream and Fat Content.

ED. HOARD'S DAIRYMAN:—In a recent issue of your paper, I notice the answer to the inquiry by W. H. S., of Barnesville, with reference to the weight of cream. This answer, although explicit, does not quite satisfy our needs. We prefer to sell cream by weight, and by weighing a given quantity as accurately as possible, we find it weighs but a very small fraction over 8 lbs, per gal. We are required to sell cream that will churn 2 lbs. of butter per gallon, so if the question be not impertinent, I will ask you to

The Cow Man

is pretty sure to be interested in the matter of milk cans. If you happen to be such a man we are favoring you by calling attention to our line of

STURGES Standard Approved Milk Cans

It is the best made line of milk cans in the world. Cans that are hedged against crushing and denting, seams soldered and tinned and retinned to shut out all chance of rust and secure perfect cleansing, and with perfect handles for convenience and security. The patterns include the famous **Iowa, Elgin, Chicago, Burn, Omaha, Wisconsin,** and other makes. Our Special Milk Can Catalogue will interest you if you want to buy the best.

We also manufacture and sell the now celebrated Dairy Queen Churn, the Boyd Cream Ripener, Success Skim Milk Weigher and a general line of Creamery and Dairy Machinery and Supplies, as well as building complete Butter and Cheese Factories equipped with the latest appliances. We handle only high grade goods and on the lowest possible margins of profit. We have separate catalogs covering the several branches of the Creamery and Dairy Supply business. Write us for anything you need and we'll mail you catalog.

STURGIS & BURN MFG. COMPANY,
Kansas City, Mo. Chicago, Ills. St. Paul, Minn.

BUHL CANS ARE NOT Like Other Milk Cans Because They Are Better

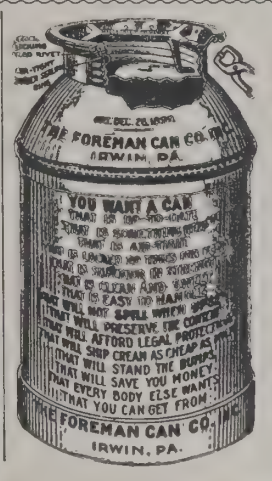
This is equally true of the **Buhl Factory, "Improved Elgin" and Genuine Iowa Cans**; superior material, design, workmanship, and smooth finish combine to produce those **long wear** qualities for which the **Buhl Cans** are so renowned. **Remember** the Buhl is the only can in the world that is made with the BUHL "VICTOR" CAN BREAST and the BUHL "VICTOR" ROUND HANDLE. They may cost a little more than common cans—we do not know, for we cannot tell how badly "the trust" and others are beating you. We know that the small added cost of the **Buhl Cans** will prove the best can investment you ever made. Every can that is stamped with our famous Milk Can Trade Mark, as shown here is a genuine **Buhl Can.** The mark is a guarantee of all around excellence. Ask your local dealer for **Buhl Cans.** If he does not have them he can get them for you. Write us about it. We will see that you are supplied.

Buhl Stamping Company, 212 W. Larned Street, Detroit, Mich.

CREAMERYMEN, DAIRYMEN and MILK DEALERS

Can be Promptly Furnished with anything they want at reasonable prices, if they will write me. My CHILDS' PATENT MILK BOTTLE FILLER is the best on the market. Send for free catalog.

J. S. BIESECKER,
59 Murray St., New York City.



BUY A LEFFEL

and you will have at once the strongest, safest and most reliable power it is possible to secure.

LEFFEL ENGINES

are made upright, horizontal, portable and on skids. They are all quick steamers, require little fuel and develop high power. 8 h. p. up. Best for creameries, dairies, skimming stations and general farm work. Send for book on *Power*.

Jas. Leffel Co., Box 120, Springfield, O.

We wish to announce that we are now operating our new factory at Irwin, Pa. Capacity—1000 cans daily, which should enable us to fill all orders promptly.

Every can sold on a guarantee.
Write for Circular H.

The Distribution of Skim Milk.....

It is known that the just complaints of creamery patrons on account of unfair distribution of skim milk are the bane of the separator creamery business. Further disputes among patrons, annoyances to managers, hindrances to the best work of buttermakers, watering the skim milk, and many other ills in the same train are unnecessary, since the

Barber-Coleman Check Pump

has for more than five years been successfully solving the problem in many different creameries. When a patron has dropped in his check he can pump the amount of skim milk called for by his check, less the percentage taken out as cream, so in like proportion to all other checks. Its measuring apparatus is just an ordinary pump which everyone understands and knows how to operate.

Cornish, Curtis & Greene Mfg. Co.,

General Sales Agents De Laval Alpha Separators,
FORT ATKINSON, WIS.

please insert in your paper the following, with a correct answer:

What would be the exact weight of a gallon of cream that would churn 2 lbs. of butter, and what per cent of butter fat should it contain? A. H.

Flushing, Ohio.

Cream that will churn out 2 pounds of butter to the gallon should contain 1.65 pounds of fat, corresponding to 19.5 per cent. Cream containing this amount of fat should weigh 8.45 pounds per gallon. We would call attention to the fact that the relation of weight to measure in the case of cream is frequently very liable to vary. The cream comes from the separator with considerable bubbles of air enclosed in it, and if the cream is thick it is impossible for the air to escape. This makes the cream lighter than it should be, and introduces a source of error when it is measured. In the above case, a gallon of 20 per cent cream should weigh 8.45 pounds, whereas the correspondent states that it weighed but little over 8 pounds per gallon, a condition of things which easily give rise to argument. Cream, when possible, should be bought and sold by weight and fat content.

Prepotency.

This very important quality in a sire has been less discussed and studied than almost anything else. Very likely this is so because of the fact that we know less concerning it than anything else. HOARD'S DAIRYMAN has picked up every thing it could find, but still the field is almost wholly an unexplored one. A writer who signs himself "Bruni" furnishes the *Australasian* the following interesting comment on this subject:

"Prepotency is the term used by stock-breeders to describe the power possessed by some sires, of stamping their progeny with their own good qualities, physical and mental. That this power is not possessed by all pure-bred sires is well known, for it is almost absent in some, and remarkably pronounced in others. Length of inheritance, though favorable to the development of prepotency, does not always confer it. Some of the most striking instances of a lack of prepotency have been furnished by animals of long pedigree, and of the most favored strains, that were themselves famous for possessing the great qualities of their race in a pronounced degree. The uncertainty that a young stud-sire will possess this power of impressing his offspring with his own good qualities, is a stumbling block in the way of the husbandman, and a weak point in the modern show system. The highest show-yard honors go to the best animal as he appears before the judges. Of his breeding and his prepotency—two of the most important points—nothing is known. Under these circumstances, it may happen that a young, well-formed animal with a weak pedigree, and untried as a sire, would receive the highest honors, while a proved sire of the greatest merit, but not as good a show animal, would be the first to be turned out of the ring. This might easily happen, as there have been many stud-sires that were too plain to exhibit and yet were of the highest excellence as stock-getters.

The following may be quoted as instances of this:—"Agricola," writing in the *Field*, on the influence of the sire in Short-horn cattle, says of Hubback "Never before or since was there such a powerful impress imparted by any sire as that which came from Hubback. It has been said that his progeny were always the same, though the cow served by him, was of the commonest. Nevertheless, Hubback is said to have been small and common in appearance." Of Jeweller, the grandson of Royal Butterfly, the same writer observes: "He was not well appreciated when living, because he was a small, shabby-looking animal, yet he was a marvellously good stock-getter." The death of Buckingham on the voyage to Ireland, was described by Carr as a national loss, and yet he was regarded by breeders as a plain, ungainly animal. On the other hand, there have been many handsome and almost perfectly shaped animals, that have proved failures at the stud. Prepotency is not indicated by the appearance of the animal; there seems to be no means of proving it save by actual experiment. This has long been recognized by the breeders of stud-sheep, who have adopted the practice of trying a very promising ram with a few ewes. Thus they make sure of some stock by him should he happen to die, and prove him as a sire should he live.

VARYING IN RACE AND INDIVIDUALS.

Prepotency varies almost as much in races (and I might almost say in species) as in individuals. In some experiments lately made in Algeria, in raising hybrids between the Indian zebu and the mongrel cow of the country, the progeny bear a much stronger resemblance to the domestic animal than they do to the zebu. The hump which is such a marked characteristic of the zebu, almost disapears in the hybrid produce. The native cow is a mongrel, while the zebu has been bred true to type for countless ages. It is not in form only that the hybrid favours its mongrel dam. It is larger than the zebu, it matures earlier, and it gives a much larger quantity of milk. That well-known writer "Agricola" gives the following description of a zebra-pony hybrid: "In general form it is said to closely resemble a horse-foal, but the top of the wither is even better formed than in ordinary foals. In the mane and tail it is decidedly horse-like, the tail being covered with long hair from its commencement, and it also resembles the horse in the expanse of the hoofs." In several parts of the United States, experiments are being made in raising hybrids between the American bison and the domestic cattle. I have seen several photos of these hybrids, and each instance they were fairly well balanced animals. The enormous disproportion between the fore and hind quarters, that is so pronounced in the bison, disappears in the hybrid. Prepotency varies greatly among the different breeds of cattle. It has always been regarded as a marked characteristic of the Hereford, an old established, but by no means the oldest breed of British cattle. In nearly all crosses with other breeds, the peculiar marking and the form of the head of the Hereford are always reproduced in the progeny. There is, however, an exception to this rule, and that is when the Red-poll is crossed with the Hereford. In this case the characteristics of the Hereford are almost entirely obliterated. The produce are either polled or snail-horned, the white face is reduced to a few white spots, often these are absent, and the form is generally that of the Red-poll. As compared with the Hereford, the Red-poll is a breed of modern origin, and yet the former, so potent in all other crosses, fails in this. Another prepotent breed is the Jersey. There can be no mistaking this cross. It is the *bete noire* of those who purchase store cattle for fattening.

CAN IT BE RECOGNIZED?

As this quality of prepotency is of such vital importance to the breeder of high-class stock (and that, every stock breeder should be), the question naturally arises, how can this quality be recognized and how defined? We must not look to the show for any assistance in this matter. In this respect the show fails completely as an educational process. An attempt has been made in this direction by the American Guernsey Cattle Club. Among several new points introduced into their new scale of points is one for prepotency in bulls. In the instructions for the judges the following remarks occur:

"This quality is in a sense difficult to perceive or describe. It is fairly indicated by vigour of appearance, strong resolute bearing, and abundant nervous energy." I cannot help thinking that this description of the quality will be of very little assistance to the judges. Prepotency is a very indefinite thing, but it has a decided existence in stock breeding. On this subject HOARD'S DAIRYMAN remarks:

"The breeders of cattle of all breeds need to give this question, how to distinguish propotency in a bull? a deal more thought and study than they have done. It is like fertility in soil, the one thing most desired." I doubt very much if any directions to judges can be drawn up that will prove effective. Many years ago, in referring to a Merino ram which I thought had been overlooked by the judges at one of our leading shows, I ventured to predict that he would prove a great sire. The result showed the folly of prophesying before you know. Notwithstanding his splendid appearance and strong masculine character, the ram turned out worthless as a sire. So far as I can see, there is no absolute proof of prepotency in a sire but the practical test in the stud, though a pedigree showing that the quality is inherited by the family, may be accepted as a good guide. The only attempt in the show system to exhibit this quality is when a prize is given for a sire with two or more of his progeny. A better test in stud sheep would be a prize for a ram and a score of his progeny, either rams or ewes.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—Butter went up half a cent on the Elgin Board of Trade today, the Quotation Committee deciding on 21½c firm.

The output for this district was 822,000 pounds. The following sales were made:

	Tubs	Sold to	Price.
East Delavan	25	Moles	21¾c.
Colvin Park	53	Moles	21¾c
Montfort	100	Sherman	21½c.

Former prices were:

	Tubs.	Price.
May 25, '03	0	21c
June 2, '02	442	22c
June 3, '01	0	18½c
June 4, '00	0	19½c

New York firm at 22c. H. C. B.

Elgin, Ill., June 1, '03.

HERE IS YOUR CHANCE!

For an "up-to-date" responsible dairyman, to rent, for term of years, a very desirable Ranch and 125 head milch cows, in one of the choicest dairy sections of California. No snow, nor yet excessive heat. Green grass the entire year. No winter feeding necessary. Freights reasonable. Apply to G. H. KELLOGG, 330 Pine St., San Francisco, Cali.

FARM FOR SALE BUFFALO, CO., WIS.

Stock and Grain. 360 acres, 200 acres cultivated. Good buildings, new, including silo. Stock, machinery, etc., included. Excellent soil. MILES & MYERS, C-100 MATTHEWS BLDG., MILWAUKEE, WIS.

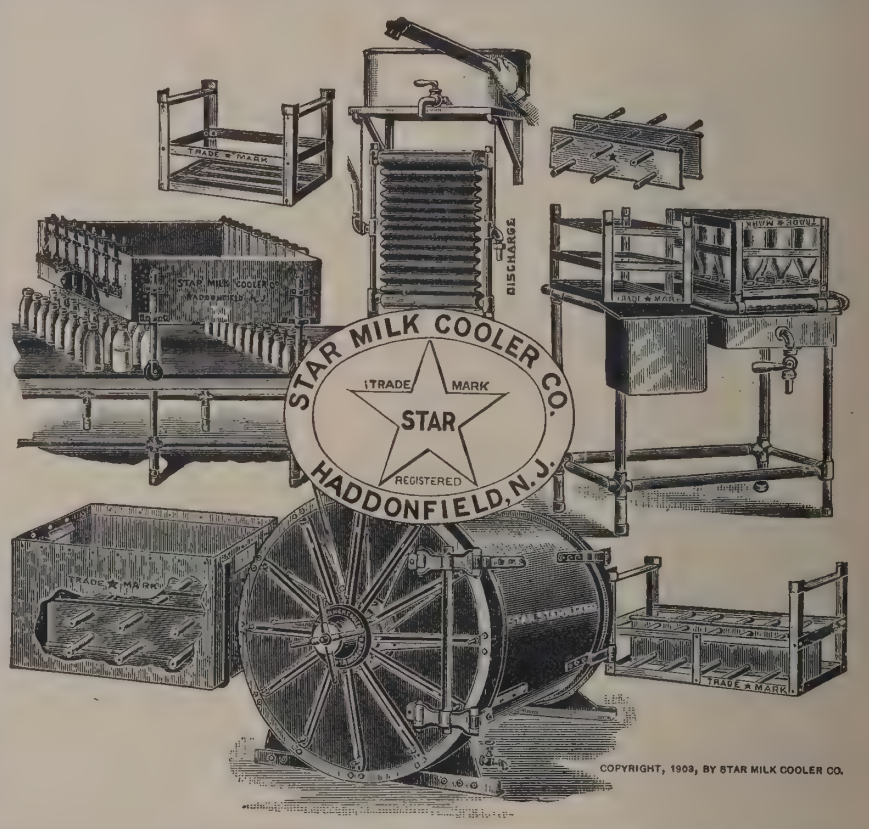
FREE TO ALL HOUSEKEEPERS

The "1900" Ball-Bearing Family Washer will be sent free

to all housekeepers who answer this advertisement, without deposit or advance payment of any kind, freight paid both ways, on 30 days' trial. Unquestionably greatest family labor saver ever invented. Saves time, expense, and wear and tear. Will do the family washing without boiling clothes, hand-scrubbing or back-breaking. Revolves on bicycle ball bearings and is therefore easiest running washer ever made. Will do two hours washing in ten minutes. Washes blankets as well as laces, absolutely clean, and without the slightest injury.

EAST PLYMOUTH, Ohio, Feb. 2, 1902. P. O. Ashtabula, O.

We have been using the "1900" Washer since May 15, 1900. Have done over 1200 washings, and I think it is good for as many more. We do family work from Ashtabula. We have used 8 different machines, and the "1900" beats them all for good and fast work and durability.—Geo. M. Burnet.



It costs nothing to try. Sent absolutely free, freight paid both ways, for a trial of 30 days. No money required in advance.

Write at once for book and particulars to

THE "1900" WASHER CO.,
219 M. State St., Binghamton, N. Y.

Steel Water Tanks

for stock, storage, dipping, wagons, etc., of shapes and capacities to meet every farm need. Best line galvanized ware made, including roofings and sidings, eaves troughs, conductors, ridge capping, etc. Sold by prominent dealers everywhere. When you buy insist on getting the "Gedge" or "Anderson" brand. If not there write us. We'll see you supplied. Gedge Bros. Iron Roofing Co., Box 482, Anderson, Ind.

STAR SANITARY DAIRY APPARATUS.

Did You Ever Keep a Record Of Your Cows?

IF SO, you have felt the need of a convenient, simple and handy Record Sheet. We have had so many requests for these Record Sheets that we concluded to get up one that would "fill the long felt want." We have a very simple and complete Record Sheet for 10 cows, one month, that is printed on heavy Manilla Paper, we can send postpaid at following prices:

Price 5c Each	6 for 20c	12 for 30c	25 for 50c

SIZE 10x16 INCHES

We also have a one cow Record Sheet, heavy Manilla paper (one month) that we will mail postpaid

Single Copy 5c	5 for 15c	10 for 25c	25 for 40c

SIZE 6x15 INCHES

FORT ATKINSON, WIS.

The Pest of Wild Garlic.

If Cows Feed on It the Milk and Butter are Tainted—Also Taints Flesh of Cattle

Hundreds of letters have been received at the botanical division of the Department of Agriculture in the past two weeks from dairymen and farmers all over the Middle Atlantic States, asking for suggestions for controlling the crop of wild garlic, which is not only damaging the milk, butter and other products of the dairy, but doing great damage in other ways.

Mr. Lyster H. Dewey, who for several years past devoted himself to a special study of this pest, says:

"This plant, which was probably introduced into this country by Germans, is propagated almost exclusively by means of secondary underground bulbs and serial bulblets. The form most abundant in this country rarely produces seed. Those small secondary bulbs or "cloves" grow to a depth of from three to ten inches under the earth and live all winter.

"The damage done by the plant is varied and includes that to animals to be butchered, as it taints the flesh quite perceptibly. One of the most serious damages done is to milk and to milk products, the cream on the milk being even more strongly tainted than the milk itself, while butter made from such cream is utterly worthless. Even cheese cannot be made from milk so tainted.

"The period of growth of wild garlic coincides almost exactly with that of rye and winter wheat. As the wheat grains and bulbs are similar, they are sometimes ground together, making the entire product of the wheat field useless. While methods of eradicating the plant have not yet been discovered, there are means of reducing the quantity and preventing the spread. Ploughing seems to be the easiest and most successful means of controlling the growth. This should be done late in the fall, the depth of the furrow varying in different soils, so as to leave as many bulbs as possible near the surface, where they will be exposed to alternate freezing and thawing. Any surviving shoots should be destroyed by early spring cultivation.

"This process, repeated for two successive years, will destroy almost entirely the most stubborn crop. Hogs confined on garlic patches in sand land will root out and destroy the bulbs. For lawns, the carbolic acid cure may be used. A few drops applied to the leaves of the plant or shoot will not kill the leaves but the bulb. On the White House lawn a large stand of the wild garlic was entirely destroyed by one application of the carbolic treatment.

"For dedorizing milk, tainted by wild garlic, a small piece of saltpetre placed in the recepticle will be successful. However, this treatment would not be healthy if pursued for long"—*N. Y. Sun.*

DAIRY MARKETS.

ELGIN, Ill., June 1.—Butter—Advanced ½c a pound on the Board of Trade to-day, being quoted at 21½c. Sales 178 tubs on call. Sales for the week in the district were 822,000 pounds.

CHICAGO, Ill., June 1—Butter—Steady; creameries, 15@21¼c; dairies, 15@18c.

Eggs—Steady; at mark, cases included, 13¾@14¼c.

Cheese—Weak; Twins, 10½c; Daisies, 11c; Young Americas, 11@11¼c.

Cattle—Prime beeves, 1,250 to 1,500 pounds, 5.30@5.55; choice to extra steers, 4.95@5.25; fair to good export and shipping steers, 4.75@4.95; medium beef steers, 4.40@4.65; plain beef steers, 4.00@4.35; common to rough, 1,000 to 1,200 lbs. 3.50@3.80; good to choice feeders, 3.85@4.75; good to choice heifers, 3.00@4.60; poor to plain stockers and feeders, 2.65@3.75; fair to good cows and heifers, 3.10@4.00; good cutting to fair beef cows, 2.40@3.10; common to good canning cows 1.40@2.35; bulls, poor to choice, 2.30@4.35; veal calves, good to fancy, 5.50@6.75; calves, common to fair, 3.50@5.25 corn-fed western steers, 3.65@5.20; Texas bulls and grass steers, 2.75@3.30; Texas steers, fair to common, 3.85@4.60.

Hogs—Good to prime heavy shipping 6 20@6.37½; good to choice heavy packing 6.05@6 25; plain to choice heavy mixed 6 00@6 20; selected butcher weights 6.20@6.35; assorted light, 150 to 195 lbs. 5.85@6.10; common to good light mixed. 5.00@6.10; thin to choice, 50 to 130 lbs., lots 5.25@5.80; stags and rough lots, 3.75@5.75.

MILWAUKEE, Wis., June 1—Butter—Creamery—extras, 21c; firsts, 18@19c; seconds, 16c; process (renovated) 16@17c; whey. 10c. Dairy, fancy, 17c; lines, fresh. 14@15c; roll, 14@15c; packing, 13c; grease, 5@6c.

Cheese—American, new, full cream—Twins, 10½@11c; Young Americas, 11@11¼c: Daisies. 11@11¼c; Longhorns, 11¼@12c; low grades, 9@10c. Brick, fancy, new, 10½@11c: low grades, 8@9c. Swiss, drum, old, choice, 15½@16c: drum, No. 2, 13@14c; Block, choice, 14@14½c; block, No. 2, 12@13c. lower.

Eggs—Strictly fresh laid, cases returned, 13½c; dirties, 12c; seconds. 11c.

NEW YORK, June 1—Butter—Receipts, 12,648 pkgs.; market firm; extra creamery, 22c; creamery, common to choice, 18@21½c; state dairy, 16@21c.

Eggs—Recipts, 25,671 pkgs.; market higher; nearby extra, 17½@18c: nearby firsts, 15½@16½c; western extra, 17½c; western firsts, 15½@16c;

Cheese—Receipts, 6,246 pkgs; market quiet; state full cream, fancy, small, colored, 10⅝c; small, white, 10⅝c; large, colored, 10⅝c; large, white, 10⅜c.

FOND DU LAC, Wis., June 1—Cheese—Sales at the Dairy Board today were 48 Twins at 10⅜c; 107 Twins at 10¼c; 290 Daisies at 10⅞c, and 165 at 10¾c. Market active.

SHEBOYGAN FALLS, Wis., May 27—Cheese—Twenty-four factories offered 2,599 boxes of cheese on the Call Board today and all except 100 Americans sold as follows: 40 Twins at 10½c; 23 at 10⅜c; 605 cases Young Americas at 10½c; 125 at 10⅜c; 422 Daisies at 11⅛c; 463 at 11c; 154 cases Longhorns at 11⅛c; 607 at 11c. Market active and bidding unusually lively.

SHEBOYGAN, Wis., May 27—Cheese—On the Call Board here today 1,960 boxes cheese were offered. All sold as follows: Twenty-four boxes Twins at 10¼c; 858 Daisies at 11c; 446 Young Americas 10½c; 90 at 10⅝c; 427 Longhorns at 11⅛c; 115 at 11¼c.

MANITOWOC, Wis., May 27 — Cheese — The sales reported to day were: 28 Twins at 10¼c; 35 at 10½c; 750 Daisies at 10¾c, and 400 cases Young Americas at 10¼c.

PLYMOUTH, May 26—Cheese-Twenty-eight factories offered 3,572 boxes to-day, and although there was quite a drop in prices over last week, all sold as follows: 196 cases Longhorns, 11¼c; 1,090 Daisies, 10¾c; 1,307 Daisies, 10⅞c; 521 Twins, 10¼c; 458 Young Americas, 10¾c. Market active and firm.

BOSTON, Mass., June 1—Butter—Creamery, western, extra, 22⅛@22¾c; western firsts, 21½@22c; dairy, 16@21½c; imitation creamery, 17@19c; ladle, 15@17c; box and print, 15@23c.

Cheese—Choice, 11½@11¾c; Wisconsin Twins, 10¾@11½c.

Eggs—Nearby, 20c: western selected, 16¼@16½c; fair to goed. 15@16c; Illinois, 16½c; western dirties, 12½@14c.

PHILADELPHIA, Pa., June 1—Butter—quiet; prints 1c lower; extra western creamery, 22½c; near by prints, 23c Eggs firm, ½c higher; fresh near by, 17c loss off; western. 17c; southwestern, 16½c; southern nominal, Cheese dull and lower; New York full creams, choice new, 11¼@11½c; fair to good new, 10½@11c.

ST. LOUIS, June 1—Poultry quiet; chickens, 10c; springs. 18@22c; turkeys, 9c for hens; ducks, 9c; geese. 3@4c. Butter quiet; creamery, 15@22c; dairy, 13@15c. Eggs lower, 13c; near by, fresh. loss off.

NEWARK, N J., June 1—Butter—Market steady at 22c.

Eggs—16½@17½c.

NEW ORLFANS, La., June 1—Butter—Market steady at 22½c; ladles 15c; renovated 17c.

CANTON, N. Y., May 30.—Cheese — Offered 50 boxes of large cheese; 2,286 Twins and 1,008 tubs of butter. Large cheese sold at 10⅛c; Twins 10¾c; Butter—22⅛c.

NEW YORK MARKET

NEW YORK, May 29.—Butter—Receipts for the week, 46,890 packages. Exports for the week, 771 packages.

Demand continues steady from all home quarters, and prices were strong with a tendency to outside rates. There is a general feeling among speculators to take on stocks of grass butter, and another week will probably show keen competition through all the dairy districts for butter good enough to go into freezers for fall and winter markets.

Sales of extra creamery were at 22¼ to 22½c, and good firsts sold at 21½ to 22c, and under grades at 18 to 21c.

Dairy make is wanted at full quotations. Ladles are in light supply and sell quickly at advanced prices. We quote:

Creamery, extra, 22@22¼c; medium, 21@21½c; poor, 18@20c Dairy, extra, 21@22c; medium, 18@20c; poor, 15@17c. Ladle, creamery, extra, 18@19c: medium, 15@16c; poor, 13@14c. Renovated, extra. 18c; medium, —— poor, 12 to 16c.

Cheese—Receipts for the week, 28,477 boxes. Exports for the week, 14,549 boxes.

Supplies this week were quickly taken by both home and export trade, and although prices were dropped a fraction, receivers were glad to get quit of this last end of fodder make cheese.

Market closes with all grades of cheese scarce and prices firm. We quote:

Full Cream, extra, 11⅛c; medium, 10½@11¼c; poor, 9@10c.

Eggs—Receipts for the week, 81,361 cases.

Fancy fresh goods hold their own and are wanted. All other grades in full supply and are lower and irregular in price. We quote:

New York & Penn., strictly fancy, per doz., 17½@18c; Northern & Western, strictly fancy, per doz,, 17c; All Sections, poor to good, per doz., 14@16c

I Have Opened a Sanitary Milk Depot in the city of Greensburg and I have a dairy farm 3½ miles south, with one large brick two story house, two tenant houses, three barns, steam engine, 25 head cows and over 300 fruit trees. I will sell the whole business and buy the milk at 12 cents per gallon. Any one interested, address EWARD'S SANITARY MILK DEPOT, Greensburg, Ind.

For Sale—2-year-old Holstein bull, his dam is by a son of De Kol 2nd, who gave under supervision of Cornell University, N. Y., 536 lbs. milk and 26.56 lbs. butter in 7 days; his sire is by a son of Pauline Paul, the champion butter cow of the world, 18669 lbs. milk and 1153 lbs. butter in 1 year; he also has the blood of Pietertje 2nd, the champion milch cow of the world, 112 lbs. in 1 day, 30318 lbs. in 1 year. Price $125. WISCONSIN LIVE STOCK ASSOCIATION, Appleton, Wis.

Position Wanted—One of responsibility for the combined work and management of manufacturing butter, cheese and process butter. Years of experience. All goods warranted. Address H, care Hoard's Dairyman. 17-3

Wanted—A married man for dairy farm. Reliable and competent. One with boys old enough to help milk preferred. Address 93, 18th Street, Milwaukee, Wis.

Wanted—To rent for a term of years, good dairy farm. Large buildings close to town in Southern Minnesota or South Dakota. C. W. WALLINE, Cambridge, Ill. 17-2

Wanted—Two good milkers at once, Germans preferred. $25.00 per month and board. A. B. NOKES, Springfield, Ill. 17-2

For Sale—The only milk route and dairy business in town of 1500 in Wyoming. Address LOCK BOX 16, Casper, Wyoming.

Practical Man Wanted—To take charge of an Indiana dairy and push sales. Single man preferred. Must be an up-to date hustler. Address "INDIANA," care Hoard's Dairyman. 17-3

Jersey Bull Calf—Can be registered. Sire has been a prize winner. Dam is a superior cow. Dairyman's price. J. BLACK, Bremen, Ohio.

Daughters of Old Paul DeKol, 14634—One two and one three years old. They are being officially tested this week. A bargain for some one. If you want them write quick. F. G. JOHNSTON & CO., Sta. B, Columbus, Ohio.

Fine Dairy Farm for Sale—231 acres within 2 miles of Madison, Wisconsin. Good set of buildings, excellent land and location that cannot be beaten. The demand for milk far exceeds the supply. The receipts from this farm last year were $4,985.co. There is a splendid chance to more than double these receipts. Ill health is reason for selling. For full description, price, etc., write C. B. CHAPMAN, Williamsburg, Virginia. 17-sp

A Good Experienced Butter Maker desires position in private creamery by middle of June. Good references. Prefer So. Dakota or Nebraska. H. YEA, Hebner, S. D.

Are You Color Blind?—If not, you will appreciate the natural golden colored product of the Guernseys. Pure bred bulls and grade heifers for sale. A. H. HINMAN, Allenville, Wis. 17-4

For Sale—Fine herd of dairy cows, three miles from Oklahoma City, O. T. Box 336. 17-2

Do You Want—A Hay Fork Returner? Every farmer having a barn should have one. A hummer for agents. Circulars free. ROONEY RETURNER CO., Box D., Independence Iowa. 50-tf

Wanted—Single man on large dairy. Only good milkers need apply. F. W. ADAMSON, Lake Bluff, Ill. 4-tf.

For Sale—De Laval "Dairy Steam-Turbine" separator, capacity 1000 lbs. per hour, used very little, in good condition. Going out of business. Address B. F. BRUNDRED, Oil City, Pa. 13-tf

Buff Jersey's latest book on Farm Stock and Dairy Work is full of practical things for practical people. The Silo, how to build and fill; ensilage, its value; soil, crops, variety and how to grow. Swine, poultry and many other subjects ably treated. Send 25c for copy. Monmouth, Ill. 47-tf

Fine Dairy Farm for Sale—Near St. Paul, Minn. 210 acres good land with ample buildings of all kinds. Page fence cedar posts. Pure bred Holstein cattle and Yorkshire swine sell readily at good prices. Good markets for all dairy products. Will sell with or without stock and other personal property. Easy terms. Enforced removal to California only reason for selling. T. S. TOMPKINS, Pasadena, Cal. 15-tf

Position Wanted—Experienced butter maker wishes to change position. Have taken Dairy Course at Ames, Iowa. Good references. Address T, care Hoard's Dairyman. 15-5

A Registered Guernsey Bull 15 months old for sale. A very fine animal. Inquire of J. S. HUNTER, Pickett, Wis. 12-tf

For Sale—Four young registered Guernsey cows, all fresh. J. E. STORY, Stanley, Wis. 11-tf

Wanted—Second-hand De Laval or Sharples Safety Hand (hand size) separators. Never mind if out of order, but must be cheap. CREAM SEPARATOR SUPPLY CO., Council Bluffs, Ia. 16-3

Young Guernsey Bulls For Sale—Whose dams are being tested for advanced registry. Will be sold and half of purchase money refunded if dams fail to qualify. EZRA MICHENER, Michener, Pa. 16 2

Wanted—A first-class butter maker who understands machinery and is a good milker. Must be a hustler and capable of managing men and not a man who needs watching. If you are a good man and want a good position at a good salary, write, stating wages expected in your first letter. Address C-5, care Hoard's Dairyman, Fort Atkinson, Wis. 16-2

Very Low Rates to California and Return—Via the North-Western Line. First-class round-trip tickets on sale July 1 to 10, inclusive, to San Francisco and Los Angeles. Favorable limits and stop over privileges and choice of routes. The overland limited, most luxurious train in the world, leaves Chicago daily at 8 p m. Less than three days en route. Drawing room and compartment cars, observation cars, dining cars, buffett-library cars (barber and bath), electric lighted throughout. Three trains a day from Chicago to the Coast through without change. Daily and personally conducted tourist car excursions to California, Washington and Oregon. For particulars apply to ticket agents Chicago & North-Western R'y. 16-7

Some Eastern Guernseys.

ED. HOARD'S DAIRYMAN:—It was my privilege early in May to see a number of the best Guernsey herds in the east, and the Editor has asked me to tell you a little something about them. On my way east, I stopped in Ohio, and looked at two small herds. Mr. A. R. Collins, Xenia, has about twenty Guernseys, nearly all descended from Glucose, purchased from the late Silas Betts, and Fair Duchess Minda 8591. The latter cow has milked up to 41 lbs. per day. Mr. Collins is now using Sir Bonny 6084, a fine three-year-old bull by Sir Fantine out of Bonnie Beauty 2nd, with a record of 16 lbs., 4.5 oz. butter in seven days and 407.3 lbs. in a year, at three years old. Mr. Wm. Conley, at Cedarville, at one time had quite a herd of Guernseys, but tempting prices have taken them nearly all away. One two-year-old, recently fresh, Miss Vanity's Rena was especially fine.

The rest of the trip I was in the company of Mr. W. D. Hoard and our next stop was at the farm of Miss Isabel S. Wilhelm, Harrisburg, Pa. This herd is called the "Paxtang" herd, and contains many excellent individuals, and has been the birthplace of many other good ones, including Procris of Paxtang, and all will remember her as one of the best cows in the Pan-American herd, and now the property of Mr. S. M. Shoemaker, of Baltimore. Sultana of Paxtang also owned by Mr. Shoemaker is now making a large record in the Advanced Registry tests, milking up to 56 lbs. per day, four months after calving. Miss Wilhelm now has at the head of her herd Ben Bishop, a son of Benjamin and Madame Bishop, 495 lbs. of butter, and mother of four tested cows. Perhaps the best cow in the herd is Golden Lass of Paxtang, and she certainly is a beauty and a large milker. She is by Sheet Anchor 2nd, Rilma of F. is another good daughter of the same bull. Miss Wilhelm recently sold Glenwood Boy of Haddon to Mrs. E. W. Strawbridge, of Moorestown, N. J.

This bull has left some fine young things in the herd, and one of them impressed Mr. Hoard and myself as a wonder. This was Dorothy Manners of Paxtang. She was soon due to freshen with her first calf and carried the largest udder I think I ever saw on a two-year-old Guernsey. Her dam, Virginia Girl was milking 35 lbs. and Glenwood Boy was out of Glenwood Girl 2nd; this heifer ought to make a good one if you can breed them. The three old cows Kitty Clover, Francesca and Princess Bonnie have all been extra good ones.

For many years the very best bulls obtainable have been used and the present herd will speak for the results. We left Harrisburg in the afternoon, and riding through most beautiful country (from the cars) white with dogwood bloom, we reached Landenburg, Pa., late in the afternoon, and spent nearly twenty-four hours with M. M. & E. J. Hollingsworth. This is now my third visit to this herd, and marked improvement shows each time. I sold them in Sir Coral, one of the best young bulls that we ever bred. An attack of pneumonia stunted him, and left him thick winded, but certainly did not hurt his breeding powers, if you are to judge by his get. He was sired by Sir Fantine out of Fantine 2nd, and his dam Coralette made for us 479 7 lbs, fat with her second calf, and was in 1896 first-prize cow at the Wisconsin State Fair. We thought so highly of her that we are now using exclusively her son, Coralette's Son.

Messrs. Hollingsworth have in this bull's heifers a great opportunity to make a large reputation for the bull. This is the home of Vega of Pan-American fame, and she has a beautiful heifer dropped last fall, sired by Sir Coral. They are using on Sir Coral's heifers a fine three-year-old-bull, Glenwood's Sheet Anchor of Haddon. He was sired by Mainstay out of Glenwood Girl 7th; 387 lbs. fat in an official test. This bull's calves look fine. They like this blood so well that they have just purchased of Mr. Gill, a calf from Arbutus of Haddon, 530.8 lbs, butter, and she in turn from Glenwood Girl 3rd, 541 lbs.

Messrs. Hollingsworth kindly drove us over to Mr. Mark Hughes' farm, one of the points of historic interest to Guernsey breeders, as being one of the great importing farms of the early '80s. Mr. Hughes still maintains a choice herd of Guernseys and at its head is Bookeeper 10th, a son of Economy, with a milk record of 8,010 lbs. Taking the train in the afternoon, we were soon at the "Haddon" farm of Mr. E. T. Gill, Haddonfield, N. J. This is known as the home of the Glenwood Girl family, and this family is, so far, the best one the breed has developed. Glenwood Girl 2nd recently suffered a fracture of the hip, but it is hoped to get at least one more calf from her. The other daughters, 3rd to 8th, are hale and hearty, and doing well. Glenwood Girl 6th is one of the greatest cows of the breed, and never looked better than now.

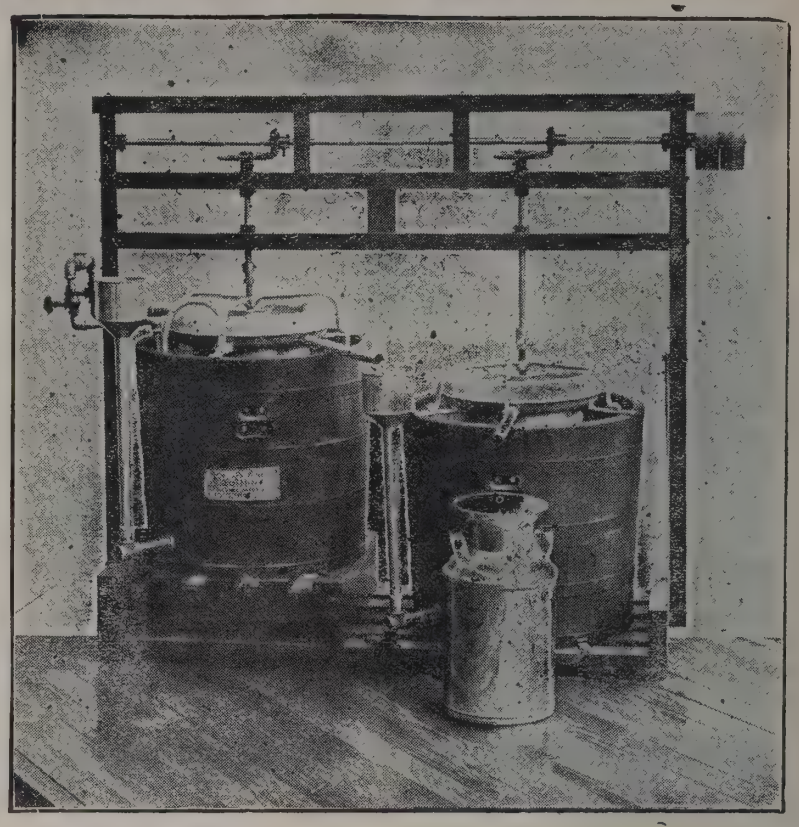
Mr. Gill has recently been inbreeding some, with excellent results. Glenwood Girl 6th has a fine bull calf by Glenwood Boy of Haddon, mentioned above, and Glenwood Girl 2nd has a fine heifer by the herd bull, Glenwood's Mainstay, a son of Glenwood Girl 6th. The fame of the herd by no means rests on this family alone for the Lucretias, Coralie of Ridgview, Nubienne and many others are grand cows. In addition to Glenwood's Mainstay, he is now using Sir Primrose, a son of Primrose Tricksey, 508 lbs. fat in the official tests, and No. 2 of the Advanced Registry.

Mr. Gill has a fine new barn, and dairy house, and is shipping large quantities of high class milk to the Abbott dairies in Philadelphia. Only six miles from Haddon Farms is Pinehurst Farm owned until his recent death, by Mr. E. R. Strawbridge, and now carefully conducted by Mrs. Strawbridge, who has always taken an active interest in the management of the herd. They have always believed in using the best bulls attainable, and have owned Mainstay, the well known son of Sheet Anchor, and Rutila's Daughter. Then they purchased Raphael of Pinehurst, a son of Lily Ella, but lost him with colic. They also used Mainsheet, a son of Glenwood Girl 4th and now are using Glenwood Boy of Haddon. The best cow in the herd is easily Auricula 2d with a record of 56 lbs. milk per day at four years old, and 12.077 lbs. at five years old.

Mrs. Strawbridge now has this cow entered for the Advanced Registery and her first month showed 53 lbs. of 4.2% milk. Selma of Pinehurst is a fine two-year-old, milking up to 30 lbs. Mrs. Strawbridge has recently purchased of Mr. Tallman, Dairymaid of Elm Place 14197, with an official record of 473.47 lbs. fat. A large lot of fine heifers give promise of future greatness for the herd.

Our next visit was to the "Florham Farms" of H. Mc. K. Twombly of Madison, N. J. The Guernsey has no better friend than Mr. J. L. Hope, the farm Supt. at "Florham." It must be conceded by everyone that no other place can equal this in its opportunity to feast one's eyes on good Guernseys. To mention half of the good ones would require a page of your paper.

The present service bulls are Rutila's Sheet Anchor, Island Champion, and May King. The two latter are imported bulls, and May King cost more money than any other Guernsey bull ever imported, or sold. All three of the bulls have wonderful good cows for mothers and only good results can follow their use.



Many good young bulls are in evidence, one of the best being sired by Rutila's Sheet Anchor and out of his own sister, Sheet Anchor's Rutila, 392.4 lbs. of fat in the official tests. These two had for a dam the great Rutila's Daughter with a record of 671 lbs. butter and the winner of many prizes. It would be impossible to say which was the best cow in the herd but most people would like Imported Charmante of the Gron 14442, as, well as any. She is a marvel in her milk machinery and is besides a great beauty. She is at work in the Advanced Registry tests, and has made 408 lbs. of fat in 202 days, and bids fair to lead all the cows in the Advanced Registry. She has a most beautiful calf by Rutila's Sheet Anchor. Pretoria 14443, five years old is doing nearly as well while Daisy Itchen 3rd, a two-year-old ought to give Dollie Bloom a good race for the two-year-old record.

It will almost discourage and bewilder a breeder to see this fine collection of Guernseys, and the only encouragement he can get out of it personally is the thought that unlimited means is at command to buy as well as breed good ones.

No herd, at least in recent years, has done so much to build up the interest in the breed as this one, and all breeders in the country wish them continued success.

Do not think for a moment that Mr. Hoard and myself can admire nothing but Guernseys, for we stopped at Cedarville, Ohio, and saw the Polled Jerseys of

A GREAT SUCCESS.

WRITE FOR OUR CATALOGUE

Mr. Orr, and on May 12th we and six or eight other Guernsey breeders attended the sale of imported Jerseys of Mr. F. S. Peer held at Hoboken, N. J. Many fine animals were sold well below their value, this being especially true of the young bulls and some of the best females sold early in the day. The cattle were not in the best of condition, but showed fine shaped udders and beautiful forms and heads of the imported type. The next day occurred the 25th annual meeting of the American Guernsey Cattle Club in New York and about 40 were in attendance. That evening off for home and work. CHARLES L. HILL.

Rosendale, Wis.

Notes on Creamery Patrons' Investigation at a Maine Co-operative Creamery.

ED. HOARD'S DAIRYMAN:—Of the number of creamery patrons, about one-third replied to the queries sent out. This one-third may be considered to be occupying advanced ground, but we will assume they are representative of the whole number and stand for the average of the patrons. The farms average 156 acres, of which approximately one-third of each is in tillage, pasture and woodland. In nearly every case pastures are permanent, and they are usually the rough lands which are unfit for cultivation. Tillage includes grass and cultivated crops, and sometimes the turf is undisturbed in a given field for as long as it yields enough to pay to mow it.

The cows are of mixed breeds, including at least seven distinct breeds. The Jersey predominates and the next most numerous strain is the Short-horn or Durham. The average number of cows reported is eight to a farm. Most of the patrons raise calves, and many are aiming at improvement of stock by breeding from the best available. A great deal can be done in this line, and in the near future, by improvements in feeding and care, and by an intelligent application of the results of a forward movement in record keeping and tests of the cows, great gains may be expected.

This is only the beginning of the rural free delivery by which dairy literature is being brought to the patron's door. The spread of information is not as catching as some other things, but it spreads and doubtless many of these patrons are destined to prove to themselves as others have done that they have not known hitherto as much about their business as they supposed they did. New standards will upset the relative values placed on the individual cows of their herds. They will realize that it does not pay to raise or feed calves from any but the cows which prove themselves best by the records.

The high prices put on the grain and seed by-products, suggests that a careful patron should try hard to substitute home grown feeds to take the place of those common feeds which have advanced to what should be made prohibitory prices on Maine farms.

Only the most concentrated of these feeds, as cotton seed meal, should be purchased, and this only when it is needed to balance up home raised feeds for balanced rations. Aim to grow legumes — clover, vetch, peas, beans and alfalfa, to feed with corn and common hay; divide the pasture and change the stock from one part to the other, thus securing a better "bite" and less travel for the cows. Raise some small areas of soiling crops in the pasture area, or adjoining the pasture, so the feeding can be done with least expense. This will supplement pasture and save "feeding on pasture" in dry times.

Among the reporters are 14 who have added the silo to their facilities for feeding, and 6 others who will build silos in the near future.

If, as assumed, these patrons are not leading those who did not answer our circular, in the near future 10 per cent of the Skowhegan patrons will be feeding cows from the silo.

If as many as that will begin to keep accurate records this year, the creamery manager can soon begin to see his business grow. This will mean some extra care and trouble, but these will be paid for in a better knowledge of what is being done, and later in better returns from better cows which will have been made better by the comparisons leading to discarding the poorest and encouraging others with more and better feed.

Maine farms are proverbially hard to cultivate, but labor saving implements must be secured and used whenever they can lighten the hard work. This is essential if patrons would produce their crops at moderate cost, and save the time from the farm operations to put into other channels, where care and thought are needed.

It appears on the table, page 304, that the average price paid for March, June, September and December, 1902, was 24½ cents per pound for butter fat. The figures for each month were 26½, 22, 23 and 26½. From the table it may be learned that some of the patrons who reported seem to have learned to have cows in full flow of milk when the price is high. Comfortable barns provided with running water help to save feed and increase the yields from cows in cold weather.

The winters are long and cold and too much of the summer's work at best must be expended in winter feeding. This serves to emphasize the need for comfortable quarters, and the tests, in order to weed out all animals that do not pay well for the great amount of time needed to feed them through the winter.

The creamery patron is of necessity a general farmer. He must raise some crops and a garden for home use. There must usually be something else for sale from the farm than milk and porkers. He is a lucky man who has tested his stock and found it to be so good that his surplus is in demand for breeding purposes by his neighbors.

The pigs are an important part of the farm income. They may have a few acres run in the summer and if care is taken to give them a clover field, a sorghum or corn patch, etc., they will do more foraging than many have believed, and require the minimum of attention.

The Skowhegan creamery is set in a region suited to the production of excellent standard winter apples. Too little attention is being given to this branch by patrons. FRANK E. EMERY.

Chicago, Ill.

Barn Questions.

ED. HOARD'S DAIRYMAN:—I am now arranging to build a dairy barn and have decided to build in accordance with plan shown in your issue of December 19th, 1902, as it is very economical as to space. I think of making the following changes: Make the 24-foot tower into a silo and put an 8 by 10 foot water tank in square between stalls which leads to calf pens, and omit the calf pens. What do you think of the changes? What inside measurement should ventilators have? How close should bottom of same be to floor and how high should they extend above the roof? Will the bent, as shown on enclosed slip, have sufficient strength to make a strong roof? I expect to use all the storage I can. At about what points on the outside should I place the fresh air duct and about what size shall I make it, and where shall I make opening for same on interior wall? I want a warm, well ventilated barn. HOARD'S DAIRYMAN has been a great auxiliary to me, and I am just selfish enough to follow its dictates to the letter. W. D. MC. K.

Brainerd, Minn.

King's rule for ventilating flues is an area of four square feet for each twenty cows. The opening at the bottom of the flue should be practically at the floor and should be provided with a register or some other arrangement whereby the opening can be closed partly or wholly as circumstances may require. There should be another opening into the flue just below the ceiling of the stable so that in summer time the hot air may be carried off through the flue. These ventilating flues should be built on the plan of a chimney and therefore extend above the ridge of the barn so as to insure a good draft without interference from the wind. The intake flues should be distributed on both sides of the stable and should not be more than ten or twelve in. square with the opening outward as far down as practicable and inward at the top of the stable. The outward opening should be not less, in any event, than three feet below the inner opening so as to prevent the warm air from passing out. It is desirable to have these flues well distributed so that the cold, fresh air in winter may be well distributed throughout the entire stable and not enter at one point and so reduce the temperature there below the average for the entire stable.

We see no reason why the proposed bent should not have sufficient strength to make a strong roof, built on the principle to be observed in constructing plank frames, but here, as in so many instances, we do not think we can serve our inquirer better than to advise him to procure a copy of King's Physics of Agriculture.

The Expert Milker.

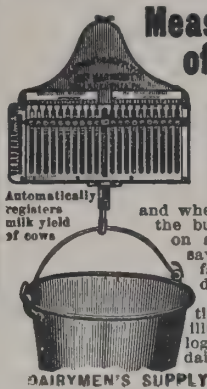
"Train up a child in the way he should go, and when he is old he will not depart from it," is a proverb which is as true now as in the days it was first written; true in practical every day duties as well as in lessons of morality, etc.

Among many neglected duties to which the farmer is prone is the one of neglecting to properly train the boys in milking. This includes more than the simple operation of drawing the milk from the cow, although that is an art. Probably not more than one in ten persons are experts; that is, thoroughly understand the art and practice it in a scientific manner.

The child should be old enough to understand the responsibility of a milker and should be taught to be cleanly as possible as to hands and clothing. A few lessons on personal neatness will give right ideas, especially if demonstrated in the habits of the teacher himself. Theory and practice should go hand in hand here. Next in importance he should be taught to properly care for the cow or cows under his care; should see that the udder be clean from soil, etc. If the udder be clean apparently, it, as well as the other parts of the body, should be well brushed to remove loosened hair, scurf, etc. The temper or temperament of the cow should be studied also. If of a nervous temperament, he should be taught to soothe and conciliate her when she is taken with one of her "moods" instead of practicing coercion with blows, remembering that it is only the justice and mercy which one of a higher organism should show toward one of the lower, to do so, besides being a matter of profit and loss. A cow will never do her best under coercion—she may be made to behave better, but that is as far as man's authority can go. Nature will outwit man every time, and the proper or normal flow will be withheld until she gets in a better humor. Many cows are yearly ruined through fear and improper treatment.

Do not send children to take their first lesson in dairying, of the hired man, unless you know him to be well trained. Ten to one he will march direct from his duties as groom, etc., at the horse stable, with his clothing full of indescribable odors and as a necessary preliminary, fill his mouth with tobacco before beginning operations.

The girls upon the farm should also receive instructions from one competent to give it. The very best milker I ever knew was a woman, and it was a positive pleasure to witness her operations. The rhymical flow as her hands would rise and fall was as enjoyable as music, and all her movements were graceful. Farmers, to you the world looks for its supply of milkmen. See to it that the next generation is properly trained and understand their business thoroughly.—A. C. MCPHERSON, in *Wallace's Farmer*.



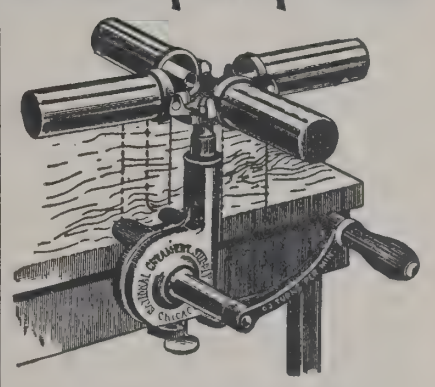
ELECTRIC

Handy Farm Wagons

make the work easier for both the man and team. The tires being wide they do not cut into the ground; the labor of loading is reduced many times, because of the short lift. They are equipped with our famous Electric Steel Wheels, either straight or stagger spokes. Wheels any height from 24 to 60 inches. White hickory axles, steel hounds. Guaranteed to carry 4000 lbs. Why not get started right by putting in one of these wagons. We make our steel wheels to fit any wagon. Write for the catalog. It is free.

ELECTRIC WHEEL CO., BOX 130, QUINCY, ILL.

Measure the Milk of each Cow



With the Automatic Milk Scale you can keep an accurate record of the yield of each cow, and remove the unprofitable ones from the dairy. Each button on scale arm corresponds to number of cow, and when pail of milk is weighed the button registers the weight on score card. Big money saver and money maker for farmers and dairymen.

Send for testimonials and illustrated catalogue of Bestov dairy supplies.

Mr. Wheaton's Canadian Dairy Notes.

Spring Cheese Receipts.—Canadian vs. Russian Butter.—Export Cheese Trade.—Cold Curing Stations for Cheese.-Refrigerator Car Service.—Meeting of Cheese and Butter Salesmen.

ED. HOARD'S DAIRYMAN:—While May, up to a couple of days ago, has been dry, the make of butter and cheese has not shown it, especially that of cheese. The receipts of cheese at Montreal from May 1 to May 19 were 48,500 boxes, as compared with 35 500 boxes for the same period of 1902. The receipts of butter do not show this advance and it looks as if our butter exports would fall behind those of last year.

The export demand for butter is not nearly so brisk as a year ago, though prices are from 1c to 1½c lower. Cable orders quote 85s to 87s, c.i.f. London, for finest creamery, or 17½c to 18c here, which is lower than can be had on the local markets. So far, however, very little full grass butter has come forward, which may have had something to do with the poor export demand.

It is felt in some quarters that Canada will find Russian butter a more formidable rival than formerly in the British market. That country is making remarkable progress in the development of her butter trade. She has a complete system of cold storage and refrigerator service between the producer and consumer, which is under direct Government control. The number of refrigerator wagons is being rapidly increased and today there are said to be 1,000 of these wagons in use in Russia. Besides these up-to-date facilities, the Russian Government has established or obtained, a flat rate of $4.12 per ton for the carriage of butter from far off Siberia to London. The only drawback seems to be in time, as it takes 15 days to cover the route. But with a complete chain of cold storage facilities such as we have described, a few days extra in time will not prove a serious obstacle.

Canadian butter, however, is of better quality than that of Russia and has already obtained a good foothold in the British market. But the advent of Russia in this field and the energy and skill she is showing both to improve quality and land her product in the best possible condition, can not be treated lightly by Canadians who wish to see our export butter trade expand.

The export cheese trade, on the other hand, seems to be moving on its way, with hardly a cloud in the horizon. With 11 to 11½c freely paid for May cheese for export, the outlook looks bright. Though the dry weather did not lessen the make, it created a sentiment in the speculative market that helped to keep up values. The rains of the past few days have been quite general and will freshen pastures and put things in good shape for a big June make. When that arrives, perhaps there may be a big slump in values, though present indications do not point that way.

All our machinery for the promotion of good dairying is in full running order. With the exception of the large increase in syndicate instruction work, referred to in our last letter, no important changes are to be noted in its operation.

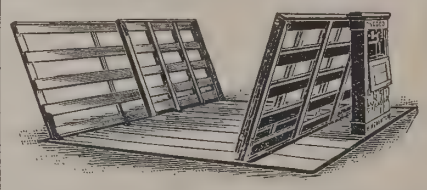
The four government cool curing stations, established at Woodstock and Brockville in Ontario and at Cowansville and St. Hyacinthe, last year, began operations a week ago. There has been a large demand from the factories for space in these stations to cure cheese, much more than the Government could supply.

These stations, last year, demonstrated the advantages of cool curing and factories are desirous of getting all the benefits from it they can. But as the space is limited they will have to do without it, or build similar stations for themselves.

If they are a good thing and will save so much in shrinkage and in improved quality, one would imagine that our factories would be sure to build similar stations for themselves. But the question of cost comes in and the most enthusiastic grow cold. With factorymen, as with many others similarly situated, the cost item is never figured out in its relation to the benefits to be derived. If ten good sized factories, by having a central cool curing station, can save one quarter of a cent per lb. on all the cheese made in one season, there should not be the hesitation there seems to be on the part of dairymen to take hold of this question.

Many of these factories, if they wish to continue in the business, will be under the necessity of providing better curing rooms. Then why not join with their neighbors and have one consolidated room for all. But our factorymen are not built that way. Foolish jealously and inborn suspicion of one another, so common in this country, prevent their doing so if nothing else will. And so they journey on very willing to lose, lest they give a neighbor the advantage. It will be so, perhaps, till the end of time. It may be that the system of syndicate instruction now so firmly established can work out a cure for this suicidal and nonsensical rivalry.

Both the Grand Trunk and Canadian Pacific Railways have commenced their refrigerator car service for the season. These cars will be run regularly from central points for butter shipment to Montreal, and will stop at important points along the route.



This refrigerator car service, which has been running for several years back, through the initiative of the Department of Agriculture, at Ottawa, has been of great advantage to our butter makers. Many, however, expect that it will do everything for them. There are a few things it will not do. It will not make bad butter good, nor will it keep butter cool that has been allowed to become overheated before being placed in the car. Last year a great deal of butter was sent forward in these cars that had been previously overheated at the creameries. To prevent a repetition of this the railway companies have received instructions not to accept butter on government refrigerator cars, that is not below 40 degrees, F., when placed in the car. This will shut out a lot of bad butter and induce creameries to provide better cold storage facilities at the factories, if they wish to take advantage of this special service.

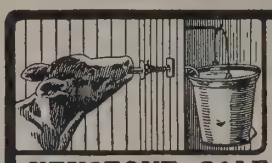
A joint meeting of cheese and butter salesmen, members of the Montreal Produce Merchants' Association, and the officials of the Dominion dairying service will be held at Montreal, on June 2nd, to consider the questions of standards of quality and descriptive terms of the different grades of cheese and butter.

Such a gathering cannot but result in some good. That more specific and uniform terms are needed in describing standards of quality, no one will deny. Still it will be hard for even so representative a gathering, as this will doubtless be, to hit upon terms and descriptions that will be applicable to all, or better, perhaps, that will be acceptable by all. Already several of the dairy boards of trade in Western Ontaria, have indicated that they will not send representatives, as any standards that may be decided upon will affect only those in the east, who send

A STRAW HAT MOVES THE BEAM.

D. E. Stone, M. D, Mt. Pleasant, Md., says: "I have used your Scales now for over a year, and am perfectly satisfied with them. If I were to pay a thousand dollars for a Scale, I could not be better suited. The Sealer of Weights and Measures said that he had never seen Scales so sensitive and accurate. When they are balanced, if you throw a straw hat on them the beam goes up. I can weigh anything from a load of hay down to a pound of butter. They entirely fill the bill, and I would not be without them."

When a straw hat will move the beam of a 5-ton scale, or when a man says that a ten-penny nail will balance them, they must be particularly sensitive—especially after they have been used for a year. But the Osgood people are used to such stories. They get them every day—thousands of pleased customers write them.



To be sensitive and stay so, a scale must be very simple. The bearings must be made of the best material. The Osgood has forged iron, steel-lined loops; tool steel pivots; patent bearings adjustable to the knife edge; heavy brass beams, double or compound; large white beam box, and many points of advantage over any other scale made.

We can furnish Stock Racks, Rack Irons, All Steel Scales, Steel Frames, and in fact everything reliable and up-to-date in the Scale line. Our prices are right. We do not try to make cheap scales, but we do make reliable scales at reasonable prices.

"Osgood on the Beam"

Is the best guarantee we can give you or which you can receive. Our terms are most liberal, and it is not our fault if every business man and farmer in this country does not have an Osgood Scale within the next year, as we will make most reasonable terms to any responsible party in the United States. A postal card will bring our catalogue and full particulars. OSGOOD SCALES CO., Central St., Binghamton, N. Y.

THE BROWN BESSIE HERD Offers one bull 14 months old, sired by Recorder, 29239, the only living son of Brown Bessie and has 14 tested daughters. Dam, Relay, 70353, test 17 pounds 2 ounces. S. E. NIVIN, Landenburg, Pa.

their cheese to Montreal for inspection.

However this may be, it looks as if some good might come out of a gathering of this kind, that would be applicable to the whole trade. If standards of quality and descriptive terms were uniform for the whole of Canada, it should aid considerably in producing a more uniform quality throughout. The outcome of the conference, will, no doubt, be watched with interest.

In a circular recently issued by the Agricultural and Dairy Commissioner, some good advice is given as to preventing the growth of mould on butter. It may be summarized as follows: Thoroughly clean the factories by liberal whitewashing with lime or the use of any other germicide; have wood work of factories dry and remove all damp and decaying pieces from the floors and gutters; look after the drainage; keep refrigerators dry and use nothing but sound wood in their make up; make butter boxes of seasoned wood and properly paraffine before using; use only good parchment paper and soak it in a solution of brine and formalin before using, and expose butter as little as possible and for as short a time as possible, in conveying it from the creamery to the railway station.

Toronta, Can. J. W. WHEATON.

CONCERNING OUR ADVERTISERS.

The Regal Gasoline Engine Co., of Coldwater, Mich., have advertisement in this issue of their small gasoline engine. They are making a small engine especially designed for dairy work 1½ and 2½ h. p. There is no purchase in machinery that proves as satisfactory and as great a saving of time and money as a good gasoline engine. Every reader of HOARD'S DAIRYMAN needs one. Write the different advertisers and get the information you need and prices.

GOOD BUGGIES CHEAP FOR THIRTY DAYS.

For one month from the date of this issue the Kalamazoo Carriage & Harness Mfg. Co., 148 Ransome St., Kalamazoo, Mich., are offering a regular $80 buggy for $45 and extending the privilege to the purchaser of trying it for thirty days and then returning it if for any reason it is not satisfactory. They do not limit the number of buggies to be sold at this price, but the time limit is inexorable, the $45 price expiring in thirty days from this date. The Kalamazoo concern is the pioneer in selling buggies direct to the people on thirty days free trial plan and have made a wonderful success of this method because of its liberality and fairness and because of the high quality, low price and good value of their goods. They are the largest manufacturers of buggies and harness in the world who sell their output direct to the users and save the middlemen's profits. Their advertisement appears in this issue and their buggy book, with all the favorites and all the newest patterns and styles of vehicles will be sent the readers on request.

Geo. T. McNeil, owner of the Elmwood Farm Holstein Herd starts ad. in DAIRYMAN this week and in writing of his herd and some recent tests he has following to say: "Mr. F. H. Richards, Cornell Agr. College, Ithaca, N. Y., recently conducted 7-day official butter test of two H. F. cows owned at Elmwood. Leila Pietertje, age 7 yrs., produced 85 3 lbs milk in one day; 577.4 lbs. in 7 days, and 21.851 lbs fat in 7 days equal to 27 lbs. 5 oz. butter 80% fat. Tulip Pietertje Inka DeKol, age 3 yrs., produced 70.1 lbs. milk in one day, 471.6 lbs. in 7 days, and 15.715 lbs. fat in 7 days, equal to 19 lbs. 11¾ oz. butter 80% fat. In justice to this heifer will state she had been milking over 60 days and had given over 3,500 lbs. milk before test began so was in very thin condition and past her best. This heifer last year made 17 2 5 lbs. butter in 7-day official test, which is the largest official record ever made in New York state by heifer under 3 years of age. As we bred this heifer it will give you an idea of class stock we produce at Elmwood."

THE GEDGE TANKS.

The galvanized steel tank manufactured by Gedge Bros. Iron Roofing Co., of Anderson, Ind., and advertised elsewhere, suggests an article of every day use on the farm. This concern is best known as a manufacturer of a superior metal roofing and siding. For several years they have been handling other makes of tanks and studying the problem of their making with the intention of bringing out a tank that should take precedence of anything on the market. The "Gedge" tank is the result. They are made round, oblong, round cornered, in fact in all desirable shapes and of any capacity from the ordinary watering trough to the large storage or tower tank for holding a water supply. Dipping and wagon tanks of approved patterns are among the list. The Gedge ad. well deserves attention of any one who is needing anything for any purpose in the tank line.

The well known preparation Chloro Naptholeum Dip manufactured by the West Disinfectant Co., of New York City, has just received an excellent endorsement from the State Veterinarian, of Wyoming. It seems that ranchmen have been having considerable trouble from mange, itch and lice in their herds, and although the laws of Wyoming are very strict in the enforcement of treatment a great deal of trouble is experienced from the fact that many, thinking that one remedy is as as good as another. The Veterinarian issues a letter to the stockmen of Wyoming calling their attention to the necessity of greater care on this point. He very strongly urges the use of Chloro Naptholeum Dip, giving his own experience as well as that of others, saving that this preparation used as directed will absolutely wipe out the trouble. It is not often that an advertised preparation receives such sweeping endorsemont.

If you have any trouble with your milk on account of the cows eating garlic or wild onions or other vegetables and weeds, look up the ad of the Virginia Cattle Food Co. They advertise "Mrs. Lea's Milk and Butter Purifier," and their goods have and are receiving the endorsement of well known men in dairy work, as well as practical dairymen. Look up their ad.

For the land's sake—use Bowker's Fertilizers. They enrich the earth and the men who till it.

70 HEAD PUBLIC SALE 70 HEAD

GREATEST OFFERING OF

HOLSTEIN-FRIESIAN CATTLE.

McADAM & VON HEYNE'S

Justly celebrated herd, will be sold at Public Auction, at the home of the World's Champions, at Brothertown Stock Farms, Deansboro, N. Y.,

WEDNESDAY, MORNING, JULY 15, 1903

This sale includes every animal in our herd. Sadie Vale Concordia, the World's Champion, with official record of 30 lbs. 10.2 oz. butter in seven days, one of her sons, now 3 years old, 2 daughters, 5 granddaughters, 1 grandson and 2 great granddaughters and sons, will go to the highest bidder. **Mercedes Julip's Pietertje,** the famous ex-champion with official record of 29 lbs. 5.3 oz. butter; her daughter and granddaughter will also be sold. Another great offering in a sire is **Canary Mercedes Johanna De Kol,** out of Canary Mercedes Brightest with official record of 21 lbs. 3 oz. at an age of 2 years and 11 months, and by Johanna Rue 2nd. Paul De Kol, who has now 13 in the Advanced Register. The four nearest dams average 23 lbs. 5.6 oz. butter in official test. They average 4 6 per cent fat. This includes record of dam made in two year form. Herd numbers

70 HEAD OF VERY SUPERIOR ANIMALS,

selected with great care. A large number being from the CELEBRATED VEOMANS HERD. All cows offered are in calf, either by Sir Pietertje Posch, a son of Alta Posch, with official record of 27 lbs. 1.4 oz. butter at 2 years and 11 months, or by Sadie Vale Concordia's Paul De Kol. or by Canary Mercedes Johanna De Kol. In this offering of fine stock are cattle suitable for the best herds, also for the improvement of good herds, as well as cattle for the beginner; as the latter, in buying any of these cattle will start right, which is an important part of the success of breeding pure bred cattle. Farm can be reached on the D L. & W. to Waterville, N. Y., or the O. & W. to Deansboro, N. Y. Trains will be met promptly and visitors conveyed to the farms. Also farms can be reached by trolley from Utica to Clinton, thence by livery. Catalogues ready early in June. Address

Mc ADAM & VON HEYNE, Deansboro N. Y.

The sale will commence promptly AT 10 A. M. WEDNESDAY, JULY 15, 1903.

COL. CAREY M JONES, Auctioneer.

LOOK HERE.

34 cows and heifers in the McGEOCH HERD have been officially tested with the following results: 10 cows average 20.26 lbs. butter in seven days; average per cent of fat 4.06. 7 four-year-olds average 16.82 lbs. butter in seven days; average per cent of butter fat 3.93. 9 three-year-olds average 15.06 lbs of butter in seven days; average per cent of fat 3.50. 8 two-year-olds average 12.16 lbs of butter in seven days; average per cent of fat 3.60. We have a few young bulls out of some of these cows, and sired by Gem Pietertje Hengerveld Paul DeKol, or Sir Ormsby DeKol for sale. One of these is out of a cow that made official record of 24.88 lbs. of butter in seven days, average per cent of fat 4.47. Are these the kind of Holstein-Friesians you wish? If so, can we not interest you in putting a bull from this class of stock at the head of your herd? McGEOCH HERD is located at Lake Mills, Wis., 56 miles west of Milwaukee. For particulars address H. B. Daggett, Mgr., Station A, Milwaukee, Wis Residence: National Ave. near 40th. Phone, South 1601.

Illinois Herd Records.

The Results of Herds "A" and "D" Compared.

ED. HOARD'S DAIRYMAN:—It is perhaps well before giving the results of another herd to compare the herds "A" and "D" (herd "D" owned by H. B. Gurler) to see if it is possible to ascertain why this great difference in performance of these herds.

In comparing the two men we find that the owner of herd "A" has given but little, if any, attention to the breeding or feeding of his dairy cows. At the end of the year's test the owner of this herd expressed himself to me in these words: "I never dreamed that such differences existed between cows. It is a revelation to me." He still claims to me that he can buy just as good cows as he can raise. If intelligence is not used in breeding and selection, this is perhaps true, but if intelligence is used in breeding and selection of his animals it is not true. This man is a hard working, conscientious, honest fellow, but he has never realized before, the importance of reading and studying. He cut his timothy hay when nearly out of its second bloom, because it cured quicker and yielded more per acre.

It never occurred to him that the early cut of timothy hay was more palatable and on this account better feed for his dairy cows, and that the total digestible matter was greater in early cut hay than in well ripened. In the selection of feed for farm animals, digestibility and palatability are two important factors to be considered. This man never gave any attention to the comparative value of feeding stuffs, but fed a ration composed mainly of corn and well ripened timothy hay. This made a ration exceptionally rich in carbohydrates and very low in protein. He has begun to realize now that he must study if he is to be a successful dairyman.

When we compare the owner of herd "D" with the owner of herd "A", we find that the former has taken a different view of things. He has studied as well as worked; he has put intelligence into his business, he has long realized the difference in dairy cows and their capabilities of producing dairy products. He has selected and retained his best cows and sold his poor ones. The comparative value of different kinds of food has attracted his attention. In short, he keeps abreast with the times and applies new ideas to his dairy, as the business man accepts new ones for his interest.

Mr. Gurler not only looks after the improvement of his herd, but he studies the comparative value of feeds and how to feed his cows so as to get the highest yields. It should be borne in mind that the owner of herd "A" took care of his own herd, while Mr. Gurler has to depend entirely upon hired help, and many times his instructions were not fully carried out. For example, some cows received more grain than they were capable of digesting and assimilating to advantage, and sometimes a cow was not milked clean.

It is a fact that a dairyman who can look after his own dairy, can get larger yields and better results than a man who has to depend upon hired help.

The following table readily shows the great differences between herds "A" and "D". An example of selection and proper feeding against unselected and improper feeding of the dairy herd, or attention and study on one hand against inattention and thoughtlessness on the other:

	Lbs. of milk.	Per cent fat.	Lbs. of fat.	Lbs. of butter.	Cost to produce 100 lbs. milk.	Cost to produce 1 lb. fat.	Profit.	Loss.
Poorest cow herd A.....	1,482	3.97	58	68	$2.07	52.2 cents.		$17.83
" " " D.....	3,399	4.58	155	181	1.03	22.4 "		.18
Best " " A.....	6,145	3.63	223	260	.50	13.7 "	$18.40	
" " " D.....	7,890	4.70	371	432	.35	7.5 "	5/.22	
Average of " A.....	3,361	3.55	119	139	.92	26.0 "		4.50
" " " D.....	5,911	4.45	263	306	.54	12.3 "	26.64	

The man who has never given any thought to the great differences in dairy cows, nor the differences between herds, may be surprised at the above figures. I am sure there are greater differences than these if it were possible to get at them. The owners of the poorest herds do not see the necessity of weighing and sampling each cow's milk for a year. In view of the above facts, what keeper of cows can afford not to know what each cow is doing for him? Would it not pay to work more with the head and less with the hands?

The owner of herd "A" who has given but little attention to the improvement of his dairy, lost $4.50 per cow per year, while the owner of herd "D" who has put thought and intelligence into his business, received a net profit of $26.64 per cow. In other words, herd "A" produced 139 lbs. of butter per cow, while the average production in herd "D" was 306 lbs. of butter.

Elgin, Ill.

Correction and Comments.

Concerning Clarified Milk.

ED. HOARD'S DAIRYMAN:—First, let me correct my statement in HOARD'S DAIRYMAN for April 17, which made it appear as if Mr. H. B. Gurler run his "certified" milk through the separator for cleaning purposes, which certainly would be unnecessary for milk as carefully handled as his. I knew his object was merely in that way to regulate the fat percentage to a certain standard, 4 per cent. But I also knew Mr. Gurler was satisfied that the centrifugal motion could have no bad effects upon the milk or its value as a food for young children.

Mr. F. L. Marion, of Massachusetts, seems to take offence at some of my little criticisms of his arguments against clarifying, and to some extent, pasteurizing. In his reply in HOARD'S DAIRYMAN of May 8, he informs his readers that "Mr. Moldenhawer shows he hadn't made a scientific study of the milk question. It was a noted New York physician, etc., who said, "clarified milk can never be milk." Well, it so happens that while I have never claimed to be a scientist on milk or anything else, still I have made an effort, and have had excellent opportunity to observe developments in the milk business, and to discuss these matters with more physicians and specialists in these lines than Mr. Marion ever had, otherwise, he would not be so narrow in his views, and be unable to see the benefit from other methods besides his own. I see that Mr. Marion's special authority he refers to is Dr. Louis Fischer, and his book on "Infant Feeding." I not only know Dr. Fisher well and have carefully studied all parts of his book relative to milk, but Dr. Fisher is not as well posted on details regarding milk and its treatment as he is on babies, a fact which unfortunately fits a great many physicians.

I called Dr. Fisher's attention to this, and upon his request wrote a carefully considered list of comments and corrections on points regarding milk, which he would make use of in the next edition of his book. The trouble is that most physicians know very well what they want, but not nearly as well what is possible or practical for the average dairyman, from whom come the great bulk of milk used for children and all purposes, by the people of small means in our large cities.

As Dr. Lyman Abbott says: "Let us rather try to find the points upon which we agree and not hunt for those where we disagree and we should get along far better." He meant this especially in religious questions, but it holds good also in many milk questions. Thus I never intended to belittle the work of those who truly try to produce an ideal, pure, raw milk and know that the more they will try to do their best in that direction, the better for the whole dairy industry, but I also know that neither Mr. Marion nor I will live long enough, to see enough such perfect milk shipped to the cities, to put it within reach of those who need it most. Ideals are nice to keep before us and aim at, but we have to deal with realities, such as today are causing milk riots and deaths of hundreds of infants in Chicago.

Let us find possible and practical methods by which all these children may obtain sweet, pure, wholesome milk, and enough of it at fair prices, and stop kicking against taking impurities out by clarifying and freeing the milk from undesirable germs by pasteurizing, if we by such means may gain the object, which never was gained by the few suppliers of ideal

The New 1903

REID HAND SEPARATOR

The 1903 Reid Hand Separator is the most exact milk skimmer ever made—it is simplest, fastest, lightest running, and affords most butter-producing material under all conditions. It creates a new source of revenue and maintains the income—

WEARS LESS, LASTS LONGEST

Every Reid Hand Separator is sent out under a positive guarantee, and is sold on its own merits. If you want a separator we will send a Reid on approval—work it ten days and if it does not excel all others return at our expense. Send for new catalogue and revised price list, mailed free.

"certified" milk. I have spoken with over 500 physicians in New York city about this pure milk question, and I can assure Mr. Marion and others that those among them who are best known and best posted do not today oppose pasteurization, properly carried out, on the contrary, endorse it. I mention among these, Dr. Emmet Holt, Prof. Northrup, Dr. Rowland Freeman, Dr. Abraham Jacobi and Dr. Park of the New York Health Board; likewise, Dr. Geo. M. Kober of Washington, D. C., one of our foremost authorities on milk hygiene, with whom I worked for 3 years when in charge of the Pasteur Milk Laboratory of Washington, D. C.

How little thought and study most physicians as yet have given to pasteurizing, and how vague their ideas about it, is best shown by the fact, that many who yet oppose a general introduction of pasteurization for the average milk supply of cities, will themselves advise mothers during warm weather, to boil or scald the milk for the baby; certainly proper pasteurization followed by rapid cooling before milk is put on the delivery wagons is a far safer and better method than heating or boiling the milk when it may have suffered considerably while in the raw state, during delivery.

These are such common sense facts, that no reasonable, open minded person would try to dispute this, even though they themselves are is a position to produce "an ideal" milk, which needs no pasteurizing. I happen to know and can easily prove it, that much milk was sold in New York City as certified by the milk commission, which never even came from a certified dairy. That thousands of babies have been saved by the milk from Nathan Strauss' pasteurized milk depots in New York, as well as by such milk from similar chartitable supplies in Chicago, Pittsburg, Cincinnati, etc., is an undeniable fact. Lately the firm supplying Mr. Strauss has adopted the best modern pasteurizer for treatment of all milk furnished him in New York and Mr. Marion will find that pasteurization will make more headway this year than ever before.

PASTEURIZED "*versus*" CLEAN MILK.

This is an unfortunate head line for an inquiry by R. H., of Greenfield, Ind., Apr. 27. Pasteurized milk should always be clean milk, and if the milk as it comes from the stable is not as clean as desirable, it certainly rather should be clarified before pasteurizing. I wondered rather at the editor's reply, that an 8-gallon can may be used for pasteurizing milk. Having practiced all methods of pasteurizing for 14 years, I can not endorse this at all, today.

The perfect cream line is an all important feature, that we will not get by heating in that way, neither do we have such a uniform treatment as is necessary to secure a uniform product. I consider next to cleanliness, uniformity the most important point for success in the milk business, as well as in the dairy business generally. Pasteurization will do much for a uniformity of our butter product, and I think it most fortunate that it is being encouraged by the government.

Canton, O. J. MOLDENHAWER.

Vetch, Cow Pea, and Soy Bean Hay as Substitutes for Wheat Bran.

[Press Bulletin.]

The object of the feeding experiments herein described was to ascertain whether hay made from hairy vetch, cow peas and soy beans, could be advantageously substituted for most of the wheat bran in the ration of dairy cows.

The following values per ton were used in calculating the cost of food:

Wheat bran, $20; vetch hay, $10; cow pea hay, $10; cotton seed, $12; cotton seed meal, $20; cotton seed hulls, $5.

Vetch hay proved fully equal in feeding value to a similar weight of wheat bran. By this substitution the cost of the food required to make a pound of butter was reduced 25 per cent, which is equivalent to a monthly saving of $22.20 in a herd of twenty cows.

With the vetch ration the cost of food for one pound of butter averaged 10 cents, in contrast with 13.4 cents when wheat bran was fed.

The waste in feeding vetch hay was, with most cows, about 6 per cent of the amount offered and with cow pea hay about 16 per cent; the latter residue, being useless is charged as a part of the ration.

That portion of the cow pea hay actually eaten proved fully equal in feeding value to a similar weight of wheat bran. Charging the cows with all the cow pea hay offered them, we find that cow pea hay had 86 per cent of the feeding value of wheat bran, one ton of this hay being equal to 1,720 pounds of wheat bran.

When wheat bran was worth $20 per ton cow pea hay was worth $17.20, and vetch hay $20.

The monthly profits per cow were $4.65 on the vetch ration and $4.35 on the cow pea ration.

One of the Jersey cows used in this test produced butter at a cost for food of only 8⅓ cents per pound, when fed on the vetch ration.

Running cow pea hay through a feed cutter did not decrease the waste in feeding this food.

Four and a half per cent more butter was produced with soy bean hay than with cow pea hay, if we take account of the portion of each actually eaten; however a larger proportion of the coarse stems of the soy bean hay was left uneaten.

When corn hearts was substituted for wheat bran the yield of butter was increased by 8 per cent. J. F. DUGGAR.

Agriculturist Ala. Exp. Sta.

Soy Beans in the Silo.

After two years' experience with the cow pea and one year with the soy bean, my conclusion was that the Large Black is the best pea to plant in the latitude of Jefferson county, Ohio (40 degs.), for the reason that while it is a bunch pea it will yield 50 per cent more than the Whippoorwill.

But I find more comfort in the Medium Green soy bean than in the peas. The same difficulty in curing presented itself in both. The short days and cool fall weather, with rains, made it a tedious harvest. So in the spring of 1902 I started out with a new thought in my mind, viz., to mix the beans in the silo with the ensilage corn. If I had it all my own way I would put one load of beans to two loads of corn, as this is nearly an approved dairy ration without the aid of twenty-dollar bran or of gluten meal, etc. To dodge this bran bill is important.

We planted our ensilage corn on May 28th. After this we prepared what had formerly been the oats ground in the rotation. Let the ground be well pulverized and settled. With the corn drill set as for ensilage corn, drill in rows thirty inches apart. Watch closely and when the beans just begin to sprout, which will be in three or four days, go over the ground with the weeder. Then after the beans are up, two cultivatings with the fine-toothed cultivator will be sufficient.

The beans were planted on the 18th of June. On September 24 we began cutting ensilage. The beans were cut the day before with an ordinary mowing machine, which cut two rows at a swath nicely. With an ordinary fork it was easily thrown on the hay wagon, and much less laborious than loading the corn but not quite so rapidly done.

At this date, April 13, I am nearing the bottom of my silo. I never had better ensilage and never had less waste. The beans kept perfectly and the cattle seemed to know no difference and would take a mouthful of the bean ensilage and eat it as greedily as the other. The bean ensilage turns quite dark; it is not so acid as the corn but is preserved just as perfectly. The beans take the place of the oats in the rotation, which is the most uncertain and least profitable crop. The beans leave the ground almost like a summer fallow and with but little work with the harrow and drag, aided by the nitrogen in the bean roots, make it an ideal bed for wheat.—RICHARD E. ROBERTS, in *Ohio Farmer*.

Wisconsin Cheese Makers' Association Meeting.

ED. HOARD'S DAIRYMAN:—The executive committee of the Wisconsin Cheese Makers' Association at the annual meeting held in Milwaukee on the 9th day of May 1903, unanimously voted to hold the twelfth annual convention in the city of Milwaukee on the 6th, 7th and 8th days of January, 1904.

Headquarters will be at the Republican Hotel, where a splendid hall and exhibition rooms will be provided for the convention.

Among other business matters given attention by the committee in the interests of the association, was the appointment of Mr. J. K. Powell of Stevens Point, Wis., as acting president, to the office made vacant through the death of President elect, Mr. Thomas Johnston of Boaz, Wis. U. S. BAER, Sec'y.

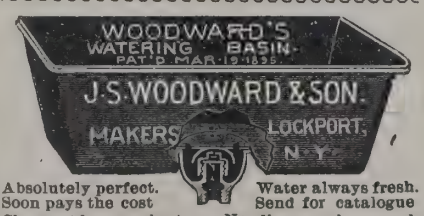
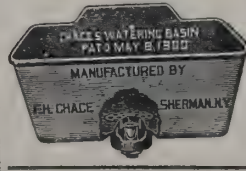
Made in 1½ H. P. and 2½ H. P. will do the work of 15 to 25 men, pump water, grind feed, saw wood, run cream separators, shell corn, etc. High grade, reliable, and easy to understand. Write for catalogue "D" REGAL GASOLINE ENGINE CO., Coldwater, Mich.



Water In The Stable a Necessity.

It is universally acknowledged that stock in the stable should have constant access to water of suitable temperature, and all progressive Dairymen are putting in some form of Watering Device. Why not use the Best? Write for descriptive circular.

C. E. BUCKLEY & CO., Poughkeepsie, N. Y.



Absolutely perfect. Soon pays the cost Cheapest because best.

Water always fresh. Send for catalogue No disease where used.

SAMPLE BASIN SENT ON APPROVAL.

Basins are fitted with Self Closing Cover which prevents all dirt and sediment from getting into them. Send for catalogue and price list

F. H. CHACE, Sherman, N. Y.

Creasey Ice Breakers

Dairymen and shippers of milk and cream find them most efficient, economical machines, and the greatest savers of time and ice. Easy to operate. Rapid cutters. The design is right.

Made in sixteen sizes to suit every requirement. Send for catalogue "11-B" which gives full particulars.

J. S. L. WHARTON, Mfr., 7th & Clearfield Sts. Philadelphia, Pa.

Cream SEPARATORS

All about them and other things for the dairy and creamery. A. H. REID, Philadelphia.

Did This Cow Have Milk Fever?

ED. HOARD'S DAIRYMAN:—Milk fever is a little rare with us since our cows are given plenty of exercise, but this spring we had one very sick cow, one of the very best cows. At night, the calf being some twelve hours old, she seemed all right. She ate a fair quantity of hay clean, and no trouble was anticipated. The next morning she was down with her head over on her back, evidently in pain and unable to rise,

A kindly neighbor said "eggs and cider with some molasses in it." She got the dose several times during the day and lay, part of the time, with her head in a natural position. The neighbor came in again at night and said I wasn't using molasses enough. He also reminded me that when he was working for me years ago I had directed him to dose a cow similarly sick with butternut root bark tea and it was a success. The cow was given eggs and cider with more molasses and my son went for some butternut roots which I at once barked and set boiling Having had great success in case of calf. scours and inflammation of the bowels with slippery elm, I put some bark of that stewing also.

Before these messes were cooked a man that was watching with the cow came in and said he guessed there were no hopes. The cow was lying out flat and her feet growing cold.

Pouring off a mixture from two kettles and cooling it till it would not scald her, went to the barn. The man's diagnosis seemed correct, as in addition to the other unfavorable symptons, she was bloating fast.

We started with a portion of the mixed tea as an injection, getting a discharge of a little blood and hard lumps of dung. The balance from the pail was poured down the cow's throat. These operations took some ten minutes, and we had barely finished when the old cow began to show signs of improvement, while the bloat was rapidly disappearing. In half an hour she was lying with her legs bent, and while she could not quite hold her head up, it was not flat out on the floor.

The mixed tea was given during the night occasionally, and also used as an injection. The slippery elm, however, was put in in greater proportion as the cow improved. In the morning she could lie naturally and her recovery was as steady and rapid as could be expected. She never had enough of butternut root bark tea to act noticeably as a physic, but the hot dose given her first undoubtedly saved her life. Half an hour in the way she was going would have finished her. If the cow had died I should have called it milk fever and said nothing, but as she recovered, I am in doubt. Will the doctor guess?

While I am writing I will say that slippery elm has cured every case of calf scours we have had in years. The little fellows will sometimes drink it of their own accord. If we think it not quite nourishing enough we add an egg or two, but a calf will live and get well on the mucilaginous tea alone. I once cured a cow that, having eaten her fill of corn meal, was flat on her side with inflammation of the bowels. I called a cow doctor and he looked her over, said I might as well have sent for him after she was dead. A pailful of slippery elm tea, part poured down and part as an injection, put her on her feet.

I once saved a colt with butternut bark tea, after he was given up. He was bound up from his birth. After the "hoss doctor" had done what he could, a neighbor stopped to look at him and consoled me by saying: "He is a good colt Rob, but he is a dead one." I was stewing some butternut bark and poured a quart down his throat, using the balance for injections. In half an hour he was on his feet and lived to be one of the best horses I ever owned. We have used flax seed, but up to date, have found slippery elm much the better of the two, and in case of trouble, needing physic, butternut root bark will have a loosening effect and at the same time, given hot, will allay pain, surprisingly.

In the case of the cow mentioned, I ought possibly to have mentioned that as she lay on the stable floor, the milk was drawn from her bag as thoroughly as possible at frequent intervals. As she is today making more butter than any other of a dozen cows she runs with, her recovery was evidently fairly complete.

Stevenson, Conn. R. S. HINMAN.

The proof of the medicine is in the recovery of the cow, but whether the trouble was due to milk fever, is another question. Milk fever is a disease with a very large death rate, and yet it frequently yields to simple remedies. How many recoveries are due to medicine and how many to the cow are unknown, and in the above case it is a far call from Wisconsin to Connecticut, and our diagnosis would probably be faulty.

Important Dairy Laws.

During the present session of the Wisconsin legislature six bills relating to different phases of the dairy industry and the state Dairy and Food Commission, have been enacted into laws, all of which, when properly executed will not only greatly facilitate the practical, beneficial results expected of the commission, but will be of untold value to the dairy interests in building up and maintaining a good reputation for clean, wholesome food products of No. 1 quality.

Chapter 43 of the laws passed is an act to prescribe standard measures for the use of the Babcock test in determining the per cent of butter fat in milk or cream; to prevent the sale of incorrectly marked implements for use in said test, and to prescribe the penalty for false determination by said Babcock test, or otherwise. The purpose of this act is to secure to patrons of creameries and cheese factories, their just dues, by compelling the proprietors of creameries and cheese factories to correctly use and read the Babcock test in determining the value of milk or cream contributed. A penalty of $25 to $100, or imprisonment in the county jail, is provided for violation of the law. The *Agriculturist* believes this act of much value to dairymen as it protects them from the fraudulent use of wrongly graduated test bottles, pippettes, etc., and will tend to bring about a state of confidence and good feeling between patron and factory. The Dairy Commissioner will enforce this law, as well as all others pertaining to his department, with promptness and vigor.

Another chapter is an act to prevent the sale of unclean and unsanitary milk and the use thereof, in the manufacture of food products, and to prohibit unclean and unsanitary conditions of creameries, cheese factories and milk dealers' establishments or outfits.

This law prohibits patrons of creameries, cheese factories or city milk dealers from supplying milk that is drawn from cows that are kept in a filthy condition, or that are kept in unclean and unsanitary barns or stables. It prohibits creameries and cheese factories from manufacturing unclean milk into food products; it prohibits city milk dealers from selling unclean or unsanitary milk; it requires creameries, cheese factories or city milk dealers to keep their premises in clean and sanitary conditions; it requires city milk dealers who receive milk or cream in cans, bottles or vessels which have been transported over any railroad or boat line, where such cans, bottles or vessels are to be returned, to empty and properly cleanse the said cans, bottles or vessels before the milk or cream contained in them shall become sour. Penalties are provided for violations of the law.

Another chapter provides for the publications of quarterly bulletins by the Dairy and Food Commissioner. A purpose of this law is to furnish dealers in food products and those who may be interested, the results of inspections and analysis of foods, with proper explanations of the same relating to the adulteration of food, drug and drink products and of dairy products so far as the same may be deemed of benefit and advantage to the public; also brief summaries of the work done during the quarter by the commissioner and his assistants in the enforcement of the dairy and food laws. It is expected that these bulletins will furnish dealers and consumers, warnings against adulterated and misbranded food products.

Chapter 133 is an act to amend section 4601 of the statutes of 1898 relative to the adulteration of drugs and foods. The amendment is in the proviso which aims to secure the labeling, branding or tagging in a manner showing their exact character and composition of food products.

Chapter 144 is an act to provide an assistant chemist and additional food, milk, dairy, cheese factory and creamery inspectors for the Dairy and Food Commission. An assistant chemist and two inspectors to be paid by the state are provided by this act. It further provides for four inspectors, paid by the Wisconsin Dairymen's Association. This latter clause seeks to clothe with police power the four instructors now employed by the Wisconsin Dairymen's Association. It will greatly increase the efficiency of these instructors to make them inspectors also. They will do as effective work for the Dairy and Food Commission as though they were paid by the state.

Chapter 187 is an act to provide for the collecting of dairy statistics. The purpose of this law is to provide complete and classified statistics relating to the great dairy industry of the state that represents a total annual income of about $55,000,000.

The legislation of the past winter greatly increases the effectiveness of the Dairy and Food Commission, and a clean-up policy among the creameries, cheese factories and city milk dealers is to be inaugurated and maintained to the fullest extent possible, with the force at command of the commission. Penalties will be imposed through prosecutions under the law where such proceeding becomes a necessity —*Wisconsin Agriculturist.*

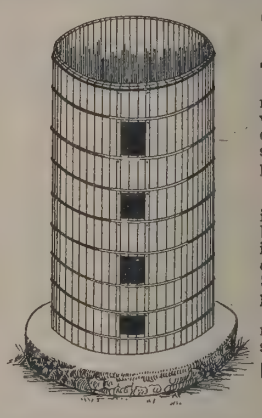
FARM FOR SALE CLARK CO., WIS.
362 acres, 125 acres under plow. All can be plowed when cleared. Well watered, land level, good soil. For particulars address
HILES & MYERS, C-100 MATTHEWS BLDG., MILWAUKEE, WIS.



Our New Patent

and Great sales are the talk of all who know of them. A fortune has been made by the patentee and the farmer in a short time. For seven months the sales were over $350 00 per day. Something good can't be gotten for nothing. By putting $500.00 and upwards into this business it will be the best paying investment we know of. Farmers using the machine say that they would not do without it for two, three, and ten times the price. Common farmer can handle it in a very paying way. We can prove the great selling qualities of this machine by bank account, the bankers themselves, and the farmer. Our plan is fair and honest. Best bank references. Car fare one way will be paid to responsible men whether they invest or not. Address
CLARENCE RAGSDALE, Moberly, Mo.
Proprietor of Magic City Stock Farm.

BLIZZARD
Feed and Ensilage **Cutter**

Does everything, cuts hay, straw, ensilage, shreds fodder and fills the silo to any height; all done by one machine. Sold on full guarantee. Write for catalogue.
Joseph Dick Agricultural Works, Box 20, Canton, Ohio.

TIME!

Its time for dairymen to act if they want the benefits of a silo this season. You should place your order **NOW** if you want the best, and the best is always the cheapest, especially in Silos. Write us for prices and circular. If you are in the market we can save you money.

Raise Your Own Cow Feed.

For the last few years commercial cow feeds, such as bran, gluten feed, cotton seed meal, oil meal and middlings have been very high in price. Last year they were particularly so. This has discouraged many dairymen from buying them. A few years ago almost every dairyman in Southern Wisconsin was buying some of these feeds. Bran used to come into Ft. Atkinson, Wis., by the train load, and dairymen bought it by the car load. The consequence was that the cows produced bountifully. According to a "cow census" of the creamery patrons, the cows of Jefferson county averaged 240 pounds of butter each; but now the returns from the creameries show a great falling off per cow. Not one-half of the dairymen of the county bought any of these feeds last year. They say they cannot afford to buy feed; that it takes all the profit to do so, and so they feed what they raise on the farm and take what they can get out of it.

In my opinion a good dairyman, with good cows, can still afford to buy commercial protein feeds and by so doing largely increase his profits. But if he can raise the proper feeds on his farm at a less expense than he can buy them, then he surely should do so. In my opinion the farmer can raise these protein feeds. In many parts of Wisconsin, and the west, Canada field peas do finely, and these, sown with oats, one and a half bushels of each to the acre, and cut for hay when the peas are about fit for table use, make a hay with about 9 per cent protein, which, with corn and oats, will make an excellent ration. Cow peas have been tried to a limited extent, and in some cases have done well. They will furnish protein.

Clover hay, if cut early and well cured, makes splendid feed, and if fed with oats for the grain part of the ration makes a well balanced ration for milk cows. But when oats are as high as they were last year, a man could sell them and buy bran even at the high price it was then, and make money by the exchange. Wherever alfalfa can be raised with success this question of raising protein feeds on the farm is solved. Alfalfa hay, if cut at a proper stage, contains 11 per cent of digestible protein. If fed with corn ensilage, it makes a perfectly balanced ration, one that is very palatable and nutritious. Nothing can beat it for milk production. In addition to the needed protein it has succulence, which is indispensable for greatest production. A little corn meal can be fed with it if there is not sufficient grain in the ensilage.

Alfalfa has been grown for many years in the semi-arid parts of the western states, but within the last few years has been tried on many farms in Wisconsin, Illinois, Iowa and other states where it was not formerly grown. Of late it seems to be proving a success. It seems to be rather a tender and delicate plant at start and needs special care to get it once started. But after it is well set, it appears to be very hardy and can stand almost anything except tramping on. Therefore, it will not bear pasturing much with heavy stock.

Bruising the crown of the root seems to be death to it. It will stand drought better than any plant I know of. The summer of 1901 was the driest ever known in southern Wisconsin. There were several small fields of alfalfa near where I live, which I watched daily. For several weeks in July and August, about the only green thing to be seen was these fields of alfalfa. Some of them were cut four times and others three times, and produced from four to six tons of the finest kind of hay to the acre, during the season. Ex-Gov. Hoard has now about 40 acres in alfalfa. Last winter his cows were fed on alfalfa hay and ensilage, with a very little bran, and there is no herd of cows in this part of the country that produced as well as his. A catch of the alfalfa can be had when the season is so dry that a catch of clover cannot be obtained. This was proved in 1901. It is best to sow it by itself on good, well prepared land, as early as possible in the spring. Sow 30 pounds to the acre. In July it will need clipping to cut off the weeds. Last summer, about the first of September, those who did this way cut it again and got from one to one and a half tons to the acre.—C. P. GOODRICH in *Prairie Farmer*.

DON'T PUT OFF

VETERINARY.

Queries in this department answered by DR. A. H. HARTWIG, Watertown, Wis.

Bloody Milk.

I have a five year-old grade Jersey. For awhile before going dry she bothered about giving bloody milk from one quarter of her bag. Went dry about three weeks. Has been fresh about two weeks now and gives bloody milk from three quarters of her bag. A READER.
Bakersfield, Vt.

ANSWER.

Try the following: Give ½ ounce of powdered ergot in food three times daily for three days, then give a teaspoonful of equal parts of dried sulphate of iron and powdered gentian root, once or twice daily until relieved.

Dysentery in Newly Born Calf.

Referring to my inquiry, and your suggestion that I more fully describe trouble with my calves, page 306, May 8th, 1903, would say that about all the information I have to give is stated in my inquiry, i.e. The calves will come all right, look well and healthy, in a day or two will becomed doopish, refusing to suck, lie around for a day or two, then die. Sometimes will have scours, usually not. I have noticed in few cases excrements are streaked with blood; their ears will droop, eyes sunken and become weak. As previously stated they are allowed to suck. R. L. R.
Spokane Bridge, Wash.

ANSWER.

Your description, as near as can be learned, answers to dysentery. Try the following;

Tincture of opium, 2 drams; tannic and salicylic acid, of each, 1½ drams. Mix and give in a pint of linseed tea to each calf affected, every three hours until relieved.

Disinfection of the entire stable is of great importance.

Red Water.

I have a cow that started to pass blood in the water 6 days before calving and is now 5 days since she freshened. L. P. K.
Pearson, Wash,

ANSWER.

Feed more nitrogenous food to make her strong, give a quart of raw linseed oil and follow this with a tablespoonful of tincture chloride of iron twice daily.

Warranted to give satisfaction.

GOMBAULT'S
CAUSTIC BALSAM

A safe, speedy and positive cure for

Curb, Splint, Sweeny, Capped Hock, Strained Tendons, Founder, Wind Puffs, and all lameness from Spavin, Ringbone and other bony tumors. Cures all skin diseases or Parasites, Thrush, Diphtheria. Removes all Bunches from Horses or Cattle.

As a **HUMAN REMEDY** for **Rheumatism, Sprains, Sore Throat,** etc., it is invaluable.

Every bottle of **Caustic Balsam** sold is Warranted to give satisfaction. Price **$1.50** per bottle. Sold by druggists, or sent by express, charges paid, with full directions for its use. Send for descriptive circulars, testimonials, etc. Address

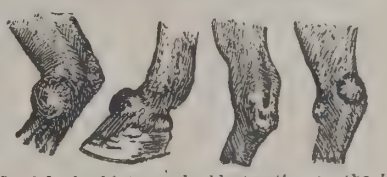
Dr. WM. HORNE, Janesville, Wis.

"Just as good?" "Just as good!" Did you say? "Just as good as Veterinary Pixine!!" The dealer who tells you this is mistaken. He does not know

FACTS AND TESTS PROVE IT!



Emery, Ky., April 9, 1903.
I feel it my duty to tell what Veterinary Pixine did for a horse of mine. He was cut with a knife between the fore legs three inches deep and two inches long, which every minute would gap open. I used several different kinds of remedy without success, even to having some stitches taken. Nothing did any good and it kept swelling and became feverish I almost gave up hopes of getting him well. In the columns of the Ohio Farmer I observed your advertisement and, as it was the last chance, I purchased a box at the druggists and used it as directed and before the box was used up the cut was entirely well. I intend to keep a supply on hand for emergency cases if it costs a dollar a box. Please accept my thanks for the good I have received from its use, and if you choose you can use my name and testimony. W. S. CAMPBELL.

This penetrating, stimulating, soothing, absorbing, antiseptic, healing ointment heals from beneath the surface by disinfecting the parts, subduing inflammation and stimulating healthy granulations, not by drying and scabbing, and stimulates growth of hair, natural color. Makes quick, clean and healthy cure; heals stinging, burning, chronic saddle and collar galls, hopple chafes, abscesses, inflammatory sores and all skin diseases. It penetrates, stimulates, soothes and heals while horse works. Money refunded if it fails.

Price, 2-oz. box 25c; 8-oz. box 50c; 5-lb. pkg. $4.00, at all druggists and dealers or sent prepaid.
TROY CHEMICAL CO., Troy, N. Y.

Some Feeding Problems Discussed.

What Should Govern the Amount of Feed?

ED. HOARD'S DAIRYMAN:—There is a question in regard to the practical value of suggesting the feeding of more protein or more nutriment to cows that have settled down to a given flow of milk, as has been the general custom. It has long since become plain to the close observer that such changes fail to bring the desired results, and that only a fresh, succulent pasture in the spring will cause the cows to make any marked change in the flow of milk and yield of dairy products. If the meal is increased during stall feeding in the winter, of if the nutritive ratio of the ration is narrowed, little benefit, if any, is derived therefrom. And it frequently occurs that the reverse of the results desired are obtained, by the cows gaining in flesh instead of in yield of milk.

Some years ago, when we were using the old herd of dairy cows in experimental work, some criticisms were indulged in by those who did not understand the situation, because we were feeding such heavy grain rations. If our work was carefully and intelligently examined it would, doubtless, be found that for nutriment consumed the yield of dairy products was very close to the maximum. The results were secured because the mammary functions of our cows had been developed to the full capacity of their feeding powers by several years of careful feeding and handling. Had we fed 14 pounds of meal per day to cows that had only the ability to digest and convert into dairy products 8 pounds, the results would have been different, and had nutriment in roughage cost less than nutriment from concentrates, the cost of production would have been different.

Now, and for several years past, nutriment in meal costs more than it does in roughage, and it is for this reason that we are feeding more roughage and less concentrates. Were we conducting a dairy solely for the profit, and not for experimental purposes, we should adjust the concentrates and roughage according to the cost of nutriment in each, feeding as much as possible of the one in which nutriment was the cheapest, and as little as possible of the one in which it was the dearest. We should also adjust the total nutriment supply to the work the cows were actually doing, and not in accord with the amount of work we thought they ought to do. That is, meal would be fed according to the dairy work they were doing and roughage to satisfy their feeding desires, seeing to it that the nutriment content of the two was enough for the production of the milk and for maintenance. In experimental work, however, this is not always practicable.

The futility of feeding a cow for a greater product than she is giving, with a view of causing her to increase in the flow of milk and yield of dairy products, was very clearly shown in the very interesting and instructive demonstration made by Prof. W. J. Fraser of the University of Illinois during the lactation year 1899-1900, with the two cows Rose and Nora. The former came into milk first and by careful feeding and skillful handling she was brought to her maximum flow in six weeks and to full feed in eight. She yielded at her best a little over 45 pounds of milk per day, and for the lactation period it averaged in round numbers, 5 per cent butter fat. When on full feed she received 16 pounds of concentrates daily, but the average during the year was 13.65 pounds, and the average daily ration contained 17.75 pounds of digestible matter. A very liberal supply indeed, but it was about what she needed. Her average daily yield was 31 pounds of 5 per cent milk. Her weight is not reported in the bulletin, but assuming that it was 1000 pounds, and that it required 7.75 pounds of nutriment for her daily maintenance, and that according to the table on page 104 of bulletin 79, Minnesota Experiment Station, it requires .3189 of a pound of nutriment for the production of one pound of 5 per cent milk and 9.89 pounds for 31 pounds, the daily ration for the work she was doing would be 17.64 pounds of digestible matter, which is within .09 of a pound of the calculated amount that she received.

When Nora came in she received a similar ration. That is, she was fed for a yield of 31 pounds of 5 per cent milk. But the 5 per cent ration did not cause her to give 5 per cent milk; she was not elaborating that kind, and we know of no ration that would make her do it. In the first part of her lactation it tested 3.3, and at the close 4, and averaged 3.84. Though fed for 31 pounds of milk, she yielded on an average only 21.26 pounds.

According to the table referred to she would need for the production of a pound of milk testing 3.8 per cent butter fat, .2677 of a pound of digestible matter, and for 21.26 pounds of milk, 5.59 pounds; and adding to this for maintenance 7.75 pounds, her daily requirements were 13.34 pounds of nutriment, being 3.31 pounds less than she received. While the cow was persistently fed for a yield of 31 pounds of 5 per cent milk, she just as persistently maintained her natural gait and gave 21 pounds of 3.8 milk.

The two cows referred to made fine records, one yielding 11,329 pounds of milk and 658.9 pounds of butter, and the other 8,121.6 pounds of milk and 364.6 pounds of butter, showing that they were handled with great skill. In citing the records of these cows no criticism is intended, but they are employed simply with a view of illustrating a point bearing upon a fundamental principle in feeding practice.

The demonstration was a most excellent one, but did Nora *require* the amount of nutriment she received to do the work that she did, or would she have done the same with a ration that would have satisfied her appetite but adjusted in nutriment content to the work she was doing?

If biddy lays an egg of medium size, can we, by increasing her ration, make her lay a large one; or, laying an egg a day, can she be so fed that she will lay two?

If bossy is so constituted that she yields milk testing 3.8, can we, by increasing, narrowing or widening her ration, make her give milk testing 5 per cent fat; or, if so constituted that she gives daily 21 pounds of milk for the time being, can she be so fed that she will give 31 pounds? If not, is it not a plain business proposition to feed according to the work she is actually doing, and thus bring the cost of production to the minimum?

Years ago, Mr. Goodrich told us that he dished out meal to each cow according to what he considered she could make good use of. Why did he not give the cows that were doing light work more meal to make them give more milk? Simply because he had been in close touch with his cows for years and had learned by experience and close observation that they would not, and could not if so disposed, respond to the increased feed. Of course he fed what was called a balanced ration, and may have attributed his great success largely to that fact. Possibly more was due to the attention he gave to each individual cow than to the nutritive ratio of the ration.

Buy You a Ticket to CROOKSTON, MINN., and call upon

The Polk County Land & Loan Company

For choice Red River Valley Farms. They pay railroad expenses if you buy from them. A few good bargains.

□ **360 acre farm,** 4½ miles from Crookston, Minn., (a city of 7,000 inhabitants), and 2½ miles from the State Experimental Farm. This is a photograph of the buildings as they are today: House is 16x24 1½ stories with an L 14x22, and a wood shed in connection 20 ft. square, all on a brick foundation. Barn 28x48, with a lean to 16x48, sheeted both inside and out. Two granaries, one 14x80, and the other 14x42. The buildings are all well painted and in very good repair, and has a fine artesian well. Every acre of this farm in under a high state of cultivation, and is well drained by a slight ravine running through the farm, merely sufficient for self drainage. The soil is a rich deep black loam with a clay sub-soil, and in every respect is considered to be one of the best farms in that vicinity. Our price on this farm is $35.00 per acre.

This is a **320** acre farm about 2½ miles south of the city, this farm is quite well improved, has a very good house of about seven rooms, 1½ stories, barn large enough for ten head of horses, also a good granary, pasture and an artesian well, also has a good well at the house, good grove around the building. This is a very choice piece of land for the price $32.50,

160 acres north-east of the city; this is all hay land, and located in a German settlement, the surrounding country is nearly all under cultivation; we consider this a good piece of land for an investment, this could all be put under the plow, if desired, Price $19.00 per acre.

EGGS FOR HATCHING

I can serve you better than ever with eggs for hatching. White, Barred and Buff Rocks, Cornish Indian Games, Dark Brahmas and many other varieties. Also Ducks and Geese. All prize winners. Write for prices. J. P. Gonigam, Ottawa, Ill

Early History of the Babcock Test.

[By Dr. S. M. Babcock, Madison, Wis. at the National C. B. Association.]

[Continued from last week.]

In early days the use of the test as a means of determining relative values in factories was opposed by many operators on account of the increased labor involved in making daily tests of each patron's milk, and indeed this was a heavy burden in large factories unless extra help was employed for the purpose. This has been materially lightened by the system of composite samples, which has reduced the necessary number of tests to two or three each month without in any way affecting their accuracy.

The profits of creameries have been materially increased as a result of the location and determination of losses in skim milk, which was entirely impractical without a test simple enough to be used upon the spot. Ten years ago the average loss of fat in the skim milk from centrifugal machines was hardly less than 0.3 per cent, and in buttermilk the loss was much more than this, and not infrequently was as much as one per cent. Some of this loss was due to poor apparatus, but most of it was due to ignorance regarding the proper management of the factory. In a creamery located within one hundred miles of this city, the average per cent fat in skim milk was found to be over 0.6. Two-thirds of this was saved by running about 500 pounds less milk through the separator per hour. This resulted in an increased yield of butter from that creamery of over sixty pounds per day, which was more than sufficient to pay all the running expenses, and converted an unprofitable business into a profitable one. This was by no means an isolated instance; such cases were quite common when no means of locating losses were available. To-day, the total loss in well managed creameries when referred to the milk handled is not more than 0.2 per cent and in many cases it is even less than this. The test has been of immense service in weeding out poor apparatus, in improving methods, and in preventing careless work in all lines of the dairy work. Not only has it been of untold benefit in the factory, but it has been almost as helpful on the farm in pointing out the profitable and unprofitble cows. So long as the churn was the only measure of quality, dairymen hesitated to incur the trouble and expense of testing individual cows, and in consequence, many of the poorest cows in a herd were never found out. There is no longer any excuse for this. Progressive dairymen and breeders of pure bred stock can now make careful studies of each cow's performance, and reject those that do not pay. The leading breeders' associations recognize this, and have either discarded the churn in their official tests, or have required the churning tests to be confirmed by tests for fat. Most of the associations have further safeguarded their tests by requiring them to be made under the auspices of an Agricultural Experiment Station, and in this way have so far as possible removed suspicion regarding them. It is noteworthy in this connection that no phenomenal tests, requiring from ten to twenty-five per cent of fat in milk, have been made since this control was established.

A review of the great advances which dairying has made during the past ten years will show that most of the progress has been brought about by a better understanding by milk producers and factory operators of the principles involved in dairy practice. The Babcock test has been an important factor in all this progress, as it has brought within the reach of every interested party a means of guarding his work In closing I may say that the appreciation which this test has received throughout the dairy world is a continual source of gratification to me. (Applause.)

DISCUSSION.

Mr. Sorenson of Minnesota: I would like to ask you what you think is the cause of the black specks in the neck of the bottle?

Dr. Babcock: The black dots in the neck of the bottle usually come from too strong acid, or having the milk too warm. It is usually particles of sugar not dissolved in the acid. If the milk is not too warm, or the acid is not too strong it will rarely occur. It can be avoided by whirling. It is entirely due to there being too strong action in the bottle when the acid is first added.

Mr. Switzer of Michigan: What class of preservaline do you use for preserving the tests?

Dr. Babcock: The tablets which contain corrosive sublimate are the ones generally used.

Mr. Switzer: There are preservalines which are recommended, so many drops.

Dr. Babcock: The liquid preservatives I think consist almost wholly of formalin. It may be sold under different names, but it is usually composed of that.

Mr. Swtizer: I find that it lessens the likelihood of black specks.

Dr. Babaock: You might add too much and in that case dilute the milk somewhat. It certainly leaves the milk in better condition for sampling than some of the others.

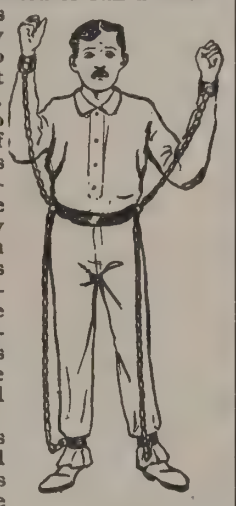
Mr. Duxbury of Wisconsin: I find complaints among the patrons who use the test at home. They say it does not agree with the test at the creamery, They will take the mflk from each cow and test it and then take an average and think that ought to be the test in the creamery, and that is an impossibility, isn't it?

Dr. Babcock: You are entirely right in that. In order to have the home tests agree with the tests at the creamery the samples should be taken from the mixed milk. An average of the per cents of fat from a number of cows is not the per cent of milk in the mixed milk.

Mr. T. H. Hart of Wisconsin: What causes the white residue to come under the fat?

Dr. Babcock: It usually comes from the acid being too weak. The black specks come from the acid being too strong, the white from the acid not being strong enough to dissolve the casein of the milk. It can be avoided by using more acid.

Mr. De Hough of Iowa: Will those tablets make sour milk sweet again?



Dr. Babcock: No, they will not. They should never be used for milk which is to be used as food. None of the preservatives will sweeten sour milk, but they will prevent milk from souring. The souring does not affect the test any. Sour milk will give just the same test as it would before it was sour, if you can get your sample with the same accuracy.

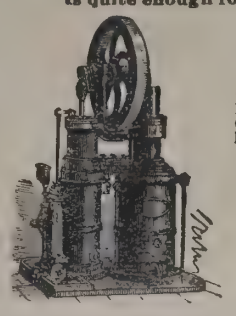
Mr. J. E. Jordan of Wisconsin: Can you get as good results by filling the bottle clear full the first time or by filling twice?

Dr. Babcock: You will separate all the fat with one whirling, but you will do bet

HANDICAPPED.

The man who started to run a race in chains and fetters would be visibly handicapped. No one would expect him to succeed. The man who runs the race of life when his digestive and nutritive organs are diseased is equally handicapped. In the one case his strength is overweighted, in the other it is undermined. Success demands above all else a sound stomach.

Doctor Pierce's Golden Medical Discovery cures diseases of the stomach and other organs of digestion and nutrition.



$3,000 FORFERIT will be paid by World's Dispensary Medical Association, Proprietors, Buffalo, N. Y., if they cannot show the original signature of the individual volunteering the testimonial below, and also of the writers of every testimonial among the thousands which they are constantly publishing, thus proving their genuineness.

"The praise I would like to give your 'Golden Medieal Discovery' I cannot utter in words or describe with pen," writes James B. Ambrose, Esq., of 1205½ Mifflin Street, Huntingdon, Pa. "I was taken with what our physicians here said was indigestion. I doctored with the best around here and found no relief. I wrote to you and you sent me a question blank to fill out, and I did so, and you then advised me to use Dr. Pierce's Golden Medical Discovery. I took three bottles and I felt so good that I stopped, being cured. I have no symptoms of gastric trouble or indigestion now."

Dr. Pierce's Common Sense Medical Adviser, sent *free* on receipt of stamps to cover expense of mailing *only*. Twenty-one one-cent stamps for the book in paper covers, or 31 stamps for the cloth-bound volume. Address Dr. R. V. Pierce, Buffalo, N. Y.

A QUICK CALL

Many times a life depends on securing immediate aid from a physician or surgeon. With a Stromberg-Carlson telephone in the house you can call the doctor in a few seconds in case of accident or sudden illness. A rural telephone line saves time and puts you in close touch with your neighbors and the rest of the world. Gives earliest market news, alarms the whole neighborhood in case of fire and helps in hundreds of other ways. The Stromberg-Carlson telephones are the easiest to operate, most modern and most durable on the market. Once tried they supercede all others. All parts guaranteed five years. Send for our Farmers' book No. F 15 telling all about Rural telephones. It is an interesting story. Sent free to anyone interested.

Stromberg-Carlson Telephone Mfg., Co., Chicago, Ill.

Weight

Salt that makes weight makes money for the butter maker. DIAMOND CRYSTAL SALT—"*the Salt that's ALL Salt*," made weight for one creamery at the rate of $8,000 a year in additional profit. The secret is simply this: Whatever weight you add in DIAMOND CRYSTAL SALT, *you obtain in increased weight of butter*. Its pure, dry flakes dissolve completely and become a part of the butter, instead of being washed out, or adhering to the worker rolls, like common, gritty, flinty salt. Our illustrated booklet "Just Salt" is just the thing for dairymen. Free on request.

DIAMOND CRYSTAL SALT CO., ST. CLAIR, MICH.

WORCESTER SALT
IS THE BEST

The largest Creamery in the world uses WORCESTER SALT, and—this telegram tells the rest:

"Kansas City, Mo., March 7, 1902.

Worcester Salt Co.,
168 Duane St., New York.

Continental won sweepstakes, also State cup trophy at Kansas Dairymen's meeting; score Ninety-Eight. Worcester Salt used ten highest scores.

G. A. McEdwards."

IT TAKES THE TO MAKE THE **BEST**

WORCESTER SALT COMPANY,
168 DUANE STREET, NEW YORK.

ter by filling it twice—that is get a clearer reading.

Mr. Crossfield of Michigan: If I take a sample of cream to test and wish it to keep for two or three days, should I leave it as cream or add the acid?

Dr. Babcock: Add the acid when you get ready to test. If you add it first the action is too prolonged and you are apt to get dark substances under the fat, which will interfere with the reading.

Mr. Haugdahl: What does each division of the scale of the Ohlsson test bottle measure?

Prof. Farrington: I will answer that. .05 of 1 per cent, or 1-20 of one per cent.

Mr. Haugdahl: That is, if the test shows one space of fat that is .05?

Prof. Farrington: Yes.

Mr. Haugdahl: Is that the actual loss in the sample?

Prof Farrington: That is another question. Each division of the scale is meant to measure .05 fat, but whether you have gotten all the fat out is a different thing.

Mr. Haugdahl: How much do we know about it?

Prof. Farrington: It depends on what temperature you run the test and the speed at which the bottle is whirled. If it is properly run and with the skim milk the bottle ought to measure nearly the amount of fat in the test, although I think there has never been a skim milk which tests less than .05 of 1 per cent.

Mr. Monrad: Isn't it safe, professor, to have about twice the amount for luck?

Prof. Farrington: In small quantities. When the regular test bottle is used in testing skim milk I always call the reading not less than 1-10 of one per cent. The directions for reading the amount of fat on the scale have always been given to read from the extreme limit of the fat—that is from the highest point where the fat touches the scale. Now this is because you read more fat than is usually within the column, and that small difference is there to compensate for the small amount of fat which is hardly ever separated. I believe in skim milks where any fat appears, the likelihood is that there is at least 1-10 per cent of fat still left. Now, I will not say there are not tests made with a closer result, but I will confess that in my own experience I have found that skim milks containing less are extremely rare.

Mr. Haugdahl: Suppose I use skim milk. If it shows up one space on the Ohlsson bottle, what will be the test of that skim milk?

Dr. Babcock: I should say it had at least 1-10 per cent in it even under those circumstances, because in the ordinary way of testing skim milk the fat globules are extremely small and separated with great difficulty, and I believe where such small quantities are recovered there is fully as much left behind. I have never found a sample of skim milk which tested less than 1-10 per cent, and the majority did more.

Mr. Brown of Missouri: In the tests you use does the steam play directly on the bottle, and if so, does it affect the tests?

Dr. Babcock: The tests I have used have never had the steam playing directly on the bottles. It would not affect the reading, I think, one way or the other.

Mr. Sollie of Minnesota: As I understand it, one space of the Ohlsson bottle is .05 per cent fat, and the professor says to read 1-10 any way. I don't understand.

Dr. Babcock: The great advantage of reading these Ohlsson bottles is getting relative measurements. I would advise all of you to read them according to the directions and judge accordingly. But when you ask the question as to how much fat there is in that skim milk, I believe the cases are rare where there is less than 1-10 fat left. Now this difference is immaterial in any sense except as you may wish to compare work from one day to another, and for that reason take your readings as you find them.

Mr. Holloway of Indiana: I would like to ask if putting the acid in and whirling the bottle once and leaving it stand over night, whether that is hurtful or not.

Dr. Babcock: It is better to finish it immediately. You would not diminish the amount of fat by letting it stand, but you are much more likely to get sediment beneath which will interfere with the reading.

Mr. Mortenson of Minnesota: What should be the specific gravity of acid in testing?

Dr. Babcock: 1.82.

Mr. Midley of Wisconsin: What should be the temperature of sweet cream to make an accurate test?

Dr. Babcock: I should think about 60 degrees.

Mr. Midley: What effect would it have on the test if the sample were cooler than the tester?

Dr. Babcock: It will not make any difference so long as you get a clear test.

Mr. Midley: What is the cause of the great variation in the color in the tube?

Dr. Babcock: It does not affect the test at all. It depends on the solids in the milk, the quantity of casein in the cream

Mr. Midley: Will a greater or less amount of acid in the cream change the color?

Dr. Babcock: Yes, it will, as more strong acid makes a darker colored fat than less acid.

Mr. Midley: Will it require less acid for testing cream than for testing milk?

Dr. Babcock: Yes, for the reason that the solids are much less in cream than in milk. There is considerable less solids not fat in the serum of cream than in the serum of milk, and consequently these solids can be held in solution by a smaller quantity of acid.

Mr. Speers of Iowa: What is the best method of taking a sample of heavy, sour cream when it comes to the factory?

Dr. Babcock: The best way is to mix thoroughly and take it by weight. You can't get a good sample by measurement It should be by weight invariably, and great care taken in mixing.

Mr. Spitzer: In reading a sample, providing it is light or dark color below, should you read anything but the fat?

Dr Babcock: No, sir.

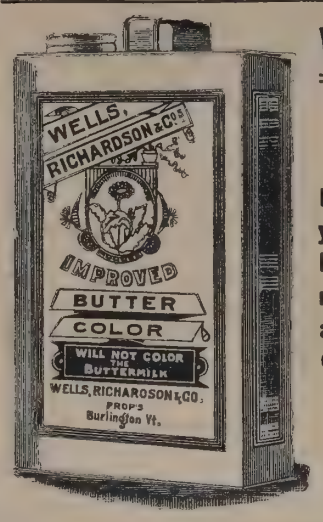
A Dairy Klondyke for Fifty Cents.

ED. HOARD'S DAIRYMAN:—I wish to call your attention to the copy of a recipe that I received by mail a few days ago:

"Attention, Farmers, Dairymen: Increase your income by learning to make one pound of butter from a pint of milk. Formula, 50 cents. This is not one of the worthless recipes advertised, but something new and reliable." Isn't that a dandy? Wouldn't we soon be able to command all the surplus cash of Uncle Samuel? Just think of it! Why, any old skate would be a common gold mine; any old cow that would give 2½ pints at a milking. 5 pints a day, 5 lbs. butter at least $1.00, $30 per month, $300 per year. Oh my! what would become of the dairyman, who after years of hard labor, hard thinking and diligent study, is all knocked out by a little 50-cent formula?

The Governor would have a veritable Klondyke, the Rockerfellers would soon be all out of biz, as the dairymen would have all of the cash in their bank accounts. There would be no cause for farmers' institutes or National Dairy Union, as the farmer would be able to knock out oleo in the first round without the aid of a ten-cent tax. But I suppose that suckers will bite and men live by their wits as long as their bait is good. I sent the good recipe to the Postmaster General at Washington, D. C. MOSSBACK.

Auburn, Wash.



CHECK YOUR SALES ON OSGOOD SCALES

Chloro-Naptholeum Dip

HOG CHOLERA is the bane of the swine raiser. It must be **PREVENTED**—that is the only absolute **CURE.** The first and only safe course for the maintenance of health in your hogs is to obtain **Chloro-Naptholeum Dip,** the great stock remedy, and our **FREE BOOK** on Swine Diseases, which gives full directions for using it. **USE** the Dip at once and freely and also **FEED** it to your swine in the slops and drinking water, disinfecting them inside as well as out. It is strictly non-poisonous to the hogs but will absolutely cure them of lice, mange or itch and prevent **HOG CHOLERA.** Lice transmit disease from animal to animal. **Chloro-Naptholeum Dip** is the most widely used preventive of Hog Cholera in existence. *Hog Cholera is unknown where* **Chloro-Naptholeum Dip** *is used regularly.* It is the safest dip and the easiest to use, requiring no heating or other preparation, coming to you **CONCENTRATED**—just put a little in a lot of water. Prices, freight prepaid: 1 gal, $1.50; 5 gals, $6.75; 10 gals. $12.50. Larger quantity at lower rates. **LOCAL AGENTS** will find a greater profit selling **Chloro-Naptholeum Dip** than any other article by the liberal terms we offer. Write us. We sell dipping tanks and sprayers at special low prices to our customers. Don't buy or build till you get our prices. **WEST DISINFECTING CO., INC., 8 E. 59th ST., NEW YORK.**

Size in Dairy Cattle.

ED. HOARD'S DAIRYMAN:—We have a herd of mixed natives, some Durham and Holstein, and have been shipping milk to Chicago. Which would be the most preferable, to cross the cattle over to Brown Swiss or Durham? We would like to raise large size cattle and have milk testing about 3.80 per cent.

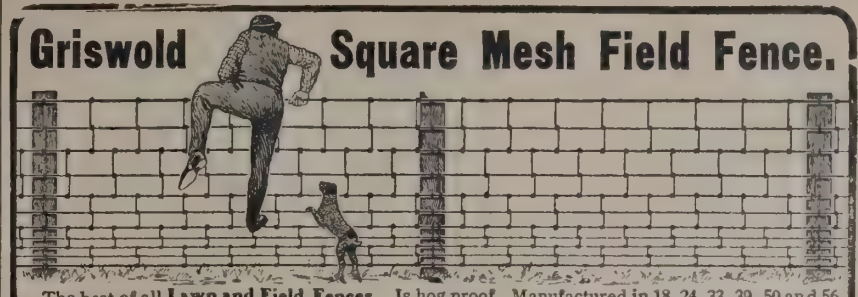
Burlington, Wis. J. J. C

HOARD'S DAIRYMAN believes in breeding dairy cattle for specific dairy purposes. After many years of close study and considerable experience, we have come to the solid conclusion that any other policy will bring loss and disappointment. All over the land are thousands of dairy herds which are a vexation and snare to their owners, because they would not hold steadfast to the central idea of selecting a bull for his ability to produce good cows, and that alone. Most of these disappointing cattle were bred, so far as any thought was given to it, for so-called "Dual-Purpose." The owner would say just as J. J. C. says; "We would like to raise larger sized cattle." The object is not to raise better cows, that will return more profit at the pail, which should always be held up as the main purpose. The result is, as might be expected, in general, a lot of unprofitable cows. J. J. C. shows by his statement that he has lost sight of the effect of true dairy breeding.

Neither the Brown Swiss nor the Durham will aid him in imparting any improvement in the dairy quality of the resulting heifers. They will both probably give him the barren result of "size" in both males and females, but that is all. If he has any hope of a better future in his herd, he will hold steadily to the dairy idea—breed for it, feed for it and handle for it, and in ten years he will have a good deal more money than he will if he chases after the will-o-the-wisp of more meat, more size. No man or set of men ever developed the dairy quality of a family of cows by breeding for size. To do so he must cross over the line into beef heredities, and all he gains in the size of the male calves, he loses, and more to, by loss in the milking power of the females. If J J C. wants milk of medium fat content with size all sufficient, he should place a Holstein bull of prepotent dairy power at the head of his herd and fight it out on that line.

Manure Tests in Massachusetts.

ED. HOARD'S DAIRYMAN:—In your issue of May 15th, I was quite interested in the article of C. I. B, in regard to the experiment of Prof. W. P. Brooks, of the Hatch Experiment Station. The results are certainly contrary to some of our ideas. I hope that the experiment will be most carefully repeated as it is quite an important question.



If both plots were plowed at the same time it may be a fact that they did not plow the same, for land where the manure is spread in the winter, retains its moisture much longer than where it is left in piles. Thus if the soil was a clay loam it may be a fact that the portion where the manure was spread in the winter was plowed too wet, and wet spring plowing is not good for the soil.

I have just been plowing a piece of land today, where part of it had the manure hauled in the winter and spread direct from the sled, and part of it had well rotted manure hauled on it about two weeks ago. Where the manure was spread in the winter, the land is a bit too wet to plow, but where it was hauled lately, the land crumbles in good shape.

Land that is to be planted for corn, I do not like to haul green manure after the first of March. That which we haul before that time, seems to give good results. As our farm is a dairy farm, and has been for thirty years, and like C. I. B. we haul so much manure it can't very well help but produce good crops. I hope that test will be repeated.

Lake Mills, Wis. W. F. STILES.

WRINGING WET Clothes dry is the reason for using any wringer. Saving clothes, buttons and money is the reason for using **Horse-Shoe Brand Wringers.** They are made with rolls of the finest Para Rubber. Every wringer is warranted. **THE AMERICAN WRINGER CO., 99 Chambers Street, New York.**

Griswold Square Mesh Field Fence.

The best of all **Lawn and Field Fences.** Is hog proof. Manufactured in 18, 24, 33, 39, 50 and 56 inch heights; in 20 and 40 rod rolls. The narrow widths can be supplemented to any height desired by Barbed or Plain wire, or two strand twisted Cable wire. Manufacturers of **Diamond Mesh Fence. Plain, Galvanized, Barbed or Telephone Wire. Wire Nails and Hay Bale Ties.** Write for illustrated catalogues and price lists. **Dillon-Griswold Wire Co., Sterling, Ill.**

Shoo-Fly THE ANIMALS' FRIEND

Kills every fly it strikes: keeps off the rest. Harmless to man or beast. Trade Mark This cow was a terror to milk prior to using ½ cents worth of Shoo-Fly. Had it been used earlier, she would not have lost milk and flesh to the amount of $14.00. The other cow was protected early and continued to give 18 qts. of milk daily through fly-time
Shoo-Fly is the original stock protector used by the same dairy-men since 1885, after testing imitations. It prevents contagious abortion and other diseases, cures all sores, scratches, skin diseases, hoof ailments, etc. **NO LICE** in poultry house or any place it is sprayed. Beware of imitations that last only a few hours and make sores. If your dealer does not keep **Shoo-Fly** (made in Philadelphia, Pa.,) send us $1.00 for latest Improved Three Tube Sprayer and enough **Shoo-Fly** to protect 200 cows. Cash returned if cows are not protected.
SHOO-FLY MF'G. CO. 1005 Fairmount Ave., Phila., Pa.
EDITOR knows from experience **Shoo-Fly** is O. K.

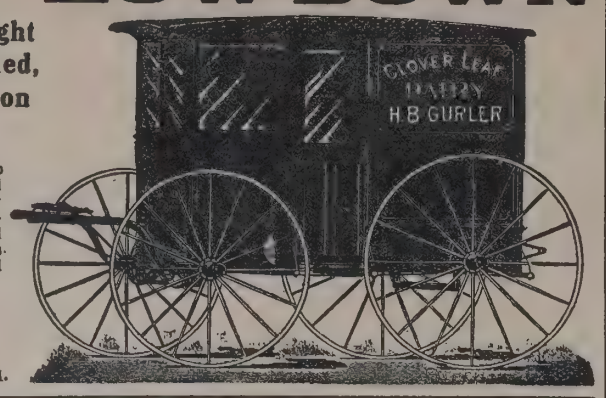
CUTTERS and BLOWERS. "They Throw and Blow"
They require less power than any other blower because the wheel containing the knives also contains paddles which throw and fans which blow. A two-horse tread power will cut and elevate 4 tons of ensilage per hour, and a 10 h.p. engine 20 tons per hour. No chains, belts or cogs to slip and waste power. Also silos, horse powers, engines, carriers, saw machines, etc.
HARDER MFG. CO., COBLESKILL, N. Y.



A CHANCE TO MAKE MONEY
I have berries, grapes and peaches a year old, fresh as when picked. I used the California Cold Process. Do not heat or seal the fruit, just put it up cold, keeps perfectly fresh, and costs almost nothing; can put up a bushel in 10 minutes. Last year I sold directions to over 120 families in one week; anyone will pay a dollar for directions when they see the beautiful samples of fruit. As there are many people poor like myself, I consider it my duty to give my experience to such and feel confident anyone can make one or two hundred dollars round home in a few days. I will mail sample of fruit and full directions to any of your readers for nineteen (19) 2-cent stamps, which is only the actual cost of the samples, postage, etc. FRANCIS CASEY, St. Louis, Mo.

LABEL
Dana's White Metallic EAR LABELS
stamped with any name or address with consecutive numbers. I supply forty recording associations and thousands of practical farmers, breeders and veterinarians. Samples free. **Agents Wanted.**

FARMER BRIGHTON, FAIRFIELD, IOWA.

CLIMAX

Ensilage and Feed Cutters.

SOMETHING DIFFERENT. CLIMAX machines are not like others. Old ideas have been discarded, and the features are exclusive and original. Some of them are

STRAIGHT KNIVES. Easy to keep in order. Cheap to replace. Cut the material more evenly and do more of it.

ELEVATING. This is done with the same wheel as the cutting. Requires less power and NEVER clogs.

SMOOTH REVERSING GEAR. With this gear there are no cog wheels to break. The machine can be stopped or reversed in an instant without danger of breakage.

SIMPLICITY. No Feed Cutter made has so few wearing parts.

IT IS MOUNTED. Being specially built on trucks, it is just the right height for feeding No platform is required.

All these features are the result of long experience. They mean easier and quicker work and better results. Send for catalogue today.

THE COMPLETE MACHINE.

WARSAW-WILKINSON CO., WARSAW, N. Y.

It pays for itself on the first crop grown after its use.

It Spreads Manure,

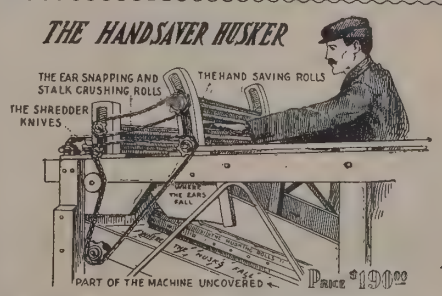
wet, dry, lumpy, caked, strawy, full of corn stalks, etc., better than it can possibly be done by hand. Spreads lime, ashes, salt, compost, etc.

THE IMPROVED

Kemp Manure Spreader

will save more hard labor, more time, more money and bring about better results than any other machine that can be employed on the farm. It trebles the value of even a small amount of manure. It is the only thing that can successfully top dress wheat in the spring, meadow lands, pastures, etc. Can be hauled onto any land easily and without injury to land, as wheels have broad tires. Can be turned on the ground it stands on, as front wheels turn entirely under. It is strong and durably made of good material and with ordinary care will last indefinitely. Greatly improved for 1903. Send for new illustrated catalogue and "How to Grow Big Crops"—Free. Remember that the only original and genuine Kemp Manure Spreader is made by us and the patents thereon have been fully sustained by a recent decision of the U. S. Circuit Court.

KEMP & BURPEE MANUFACTURING CO., BOX 46, SYRACUSE, N. Y.



New American Manure Spreaders

hold from 50 to 100 bushels. Spread just as thin or thick, fine or coarse, as ground requires. Don't have to stop team to make change. Most substantial, largest capacity, lightest draft.

DID YOU GET A COPY?

Nearly 400,000 copies of our illustrated dairy paper named "The Separator" were recently mailed to the farmers and dairymen on our mailing lists. If you are not on the list please send us a postal card and will mail you a copy at once. It is a useful paper, illustrated in colors and costs you nothing. It is both amusing and instructive, a good paper for every member of the family. It tells many interesting truths about dairying, all about the growth of the separator industry and how to buy a reliable cream separator. It gives a description of the largest cream separator works in the world where the famous TUBULAR DAIRY SEPARATORS are made at the rate of more than one hundred each day, and demonstrates why the TUBULAR is such a popular machine. It explains how to make cows profitable and shows the difference between making money by using a TUBULAR DAIRY SEPARATOR and losing money by going without one.

We have a limited number of "The Separator" left over and will be glad to mail you a copy. We will also be pleased to mail you a catalogue descriptive of the **Tubular Dairy Separators.** Ask for catalogue No. 144.

Dairy Cows on Trial. Some Interesting Experiments in England.

Under the auspices of the Agricultural Committee of the Somerset County Council some interesting experiments with dairy cows have been recently carried out in the South of England. In these trials the objects aimed at were to ascertain:

(1) Whether the principle of feeding dairy cattle in proportion to their live weight is a sound one.

(2) Whether there is any advantage to gain by mixing the milks of Short-horns and Jerseys, and in what proportions.

(3) What are the relative merits of Short-horns and Jerseys as butter producing breeds.

In the first of these experiments each cow in the herds tested—Jerseys and Short-horns respectively—was fed in accordance with her live weight as a whole. Grass could not, of course, be estimated, but the limited quantity of cotton cake fed during the summer was duly apportioned. In the first two winter months (October and November) the ration was distributed thus:

	Short-horns.	*Jerseys.*
Cut hay and chaff	23 lbs.	17 lbs.
Long hay	4 "	3 "
Decorticated cotton cake	6 "	4 "
In December it was altered to:		
Hay (part given as chaff)	12 "	8 "
Oats straw (part given as chaff)	12 "	8 "
Mangels and carrots	30 "	20 "
Decorticated cotton cake	4 "	2½ "
Bean meal	3 "	2 "
Crushed oats	2 "	1½ "
	63 "	42 "

The Short-horns in milk throughout the season yielded an average of 678 gallons per cow, while the Jerseys for the same period gave an average of 468 gallons per cow.

The problem for buttermakers, however, was not so much the milk yield as the weight of milk required to produce 1 lb. of butter. To determine the value of the milk of each breed for buttermaking, a series of tests was made every fortnight throughout the year. Two hundred and sixty gallons of milk were used in these tests, one-half Short-horn, the other half Jersey. The Short-horn milk produced 47 lbs. 12½ oz. of butter; the Jersey 68 lbs. 12¾ ozs. That is to say, the average butter ratio of the Short-horns was 27.13, or nearly 2¾ gallons of milk for each pound of butter, while that of the Jersey was 18.89, or less than 2 gallons of milk to make one pound of butter. The results may be summarized thus:

	Short-horns	*Jerseys*
Average live weight, lbs.	1,318	953
" milk yield gals.	678	468
" butter ratio of milk,	27.13	18.89
" yield of butter, lbs	250	248

As these figures show, the two breeds gave practically the same amount of butter. The question arises, however, whether if, cow for cow, they are equal as butter producers, they are equally costly to feed. Regulating the quantity of feeding stuffs in proportion to the live weight of the animal, it is shown that the Short-horn yield of butter per 1,000 lbs. live-weight, was 189 lbs. per annum, while that of the Jersey per 1,000 lbs. live weight was 290 lbs.

A further series of tests was made with the object of ascertaining the butter ratios of Short-horn and Jersey milks, mixed in varying proportions. It should be stated that the results of seven months only are available, and it would be undesirable to attempt to draw definite conclusions. The results obtained so far are as follows:

All Short-horn milk (actual butter ratio)	27.13
80 per cent Short-horn milk (actual butter ratio)	22.65
60 per cent Short-horn milk (actual butter ratio)	21.22
50 per cent Short horn milk (actual butter ratio)	21.86
40 per cent Short-horn milk (actual butter ratio)	19.97
20 per cent Short-horn milk (actual butter ratio)	19.85
All Jersey milk (actual butter ratio),	18.89

As these figures show, in all cases more butter was obtained from the mixed milk than would have been obtained if the two kinds had been churned separately. As indicating the economic importance of this point to the butter maker, it is shown that the addition of only 20 per cent of Jersey milk to that of the Short-horn, increases its value by 1d per gallon. Thus, on a basis of 15d per lb. for the butter, we have:

Value of milk for butter making per gallon:

All Short-horn milk	5.52 d
80 per cent Short-horn, 20 per cent Jersey	6.62 d
60 " " " 40 " " "	7.06 d
50 " " " 50 " " "	6.86 d
40 " " " 60 " " "	7.59 d
20 " " " 80 " " "	7.55 d
All Jersey milk	7.94 d

—Farmers' Gazette.

You have noticed the disagreeable odor of clothes just from the wash. That's the soap. Cheap soaps do not rinse out. Their objectionable ingredients adhere to the fabric. Ivory Soap rinses readily, and because of its purity leaves the clothes sweet and absolutely odorless.

IT FLOATS.

Dairy Laws

The following is a synopsis of a portion of the Minnesota dairy laws, as they appear after revision by the last legislature. They apply especially to creameries and creamery patrons, and are worthy of careful consideration.

Especial attention is called to the fact that milk intended for the market must not be kept in stables, and that all creameries must pasteurize their skim milk, and that anyone that under-reads the Babcock test is liable to a fine of $25.00.

No person shall offer for sale unclean, impure, unhealthful, unwholesome or adulterated milk or cream, or any milk or cream that has not been well cooled, aerated, or to which preservatives of any kind have been added.

No person or firm shall keep cows for the production of milk for market, in a crowded condition, or in stables which are not perfectly ventilated and lighted, or which are filthy from an accumulation of animal refuse, or from unsanitary surroundings; nor shall milk for such purposes be drawn from cows which are themselves in a condition of filth or uncleanness, or from cows which are affected with tuberculosis, ulcers, running sores, or any other form of disease, or from cows which are fed wholly or in part upon distillery waste or brewery grains, or the waste of vinegar or garbage or that of sugar factories, or food not properly preserved in silos, or garbage or decayed food of any form, or upon any other form of food which will produce milk which is unhealthful or unwholesome; or from cows within fifteen days before and five days after parturition. Nor shall milk or cream be produced for such purposes be kept in the stable, or in a place where bad or contaminating odors exist, and all milk or cream thus produced is declared to be unclean, unhealthful and unwholesome. This shall not be construed to prevent the feeding of ensilage, from silos, when properly preserved.

Any milk which is shown by analysis to contain any substance or substances of any character whatever, not natural or normal constituents of milk, or to have been deprived, either wholly or in part, of any constituents naturally or normally contained in milk, or which is shown to contain more than 87 per centum of water fluids, or less than 13 of milk solids, of which not less than three and one-half per centum shall be fat, is declared to be adulterated milk.

All cream that shall contain less than twenty per centum of fat, or shall contain any added thickener, or foreign coloring matter, shall be deemed to be adulterated.

All creamery or dairy butter that shall contain more than sixteen per centum of water shall be deemed to be adulterated.

No person, firm or corporation shall manufacture from unclean, impure, or unhealthful or unwholesome milk, or of cream from the same, any article of food.

All creameries before delivering to any patron, skimmed or separated milk shall have pasteurized the same at a temperature of at least 180 degrees Fahrenheit.

It shall be the duty of the dairy and food commissioner to cause the inspection of all creameries, cheese factories and all other places or buildings where dairy products of any nature whatever are produced, manufactured, stored or kept for sale, at such times as it may be deemed best, and he shall have authority to require the construction of necessary drains or improvements, to correct any unsanitary or improper conditions, either in the manufacture, storage or sale of said products, and give such instructions as will cause the improvement of any such conditions as may be found to exist that he may deem should be changed for the public good, and to cause all such conditions to be fully complied with.

It shall be unlawful for the owner, manager, agent or any employee of a creamery or cheese factory to manipulate or under-read the Babcock test, or any other contrivance used for determining the quality or value of milk.

No person, or his agents or servants, shall sell, or bring to be manufactured, to any butter or cheese factory, any milk diluted with water, or any other substance whatever, or any from which any cream has been taken (except pure skim milk to skim cheese factories), or shall keep back any part of the milk known as strippings, or shall bring or supply milk that is sour, to any butter or cheese manufactory.

No butter or cheese manufactories, except those that buy all the milk they use, shall use for their own benefit, or allow any of their employes or any other person to use any of the milk or cream brought to said manufactories, or the product thereof, without the consent of the owners thereof.

Every butter and cheese manufacturer, except those who buy all the milk they use, shall keep a correct record of all the milk received, and of the number of pounds, and packages of butter, the number and aggregate weight of cheese made each day, the number of packages of cheese and butter disposed of, which record shall be open to inspection to every person who delivers milk to such manufacturer.

Whoever violates any of the provisions of this act shall be guilty of a misdemeanor, and upon conviction thereof shall be punished for each offence by a fine of not less than $25.00 nor more than $100.00, or by imprisonment of not less than thirty days, nor more than ninety days.

Wash for Dairy Buildings.

In a German periodical appears a formula for a wash which can be applied to lime walls and afterward becomes waterproof so as to bear washing. Resenschek, of Munich, mixes together the powder from three parts broken marble and sandstone, also two parts of burned porcelain clay, with two parts freshly slaked lime, still warm. In this way a wash is made which forms a silicate if often wetted and becomes after a time almost like stone. The four constituents mixed together give the ground color, to which any pigment that can be used with lime is added. It is applied quite thickly to the wall or other surface; let dry one day, and the next day frequently covered with water, which makes it waterproof.

This wash can be cleansed with water without losing any of its color; on the contrary, each time it gets harder, so that it can even be brushed, while its porosity makes it look soft. The wash or calcimine can be used for ordinary purposes as well as for the finest painting. A so-called fresco surface can be prepared with it in the dry way.

For a useful lime wash for wood and stone, the following is a good preparation:

Twenty quarts of quicklime are slaked in a suitable vessel with as much hot water as will stand at a level of six inches above the lime. The milk of lime is diluted, and first 15 grains of sulphate of zinc and then 7 grains of common salt are added. The latter causes the lime wash to harden without cracking.

Bacteriology in Relation to Dairying.

[By Dr. W. T. Connell, Bacteriologist, Dairy School, Kingston, at Eastern Ontario Dairymen's Convention.]

It has been my privilege to come before the meetings of this Association for the past six years, and I do so again this year with a great deal of pleasure, as it affords me another opportunity to speak on the old topic of Bacteriology in some of its various relationships to the great business of dairying. It is true that a great deal of what I am going to say has been said before and in various forms, but I trust it will be of benefit to those who are not up in the subject. The particular subject which will claim my attention this morning is "The effects of cleanliness and control of temperature on bacterial contents of milk and upon its quality as affecting the manufacture of butter and cheese."

Milk, no matter how cleanly a person may be in milking, will, in practically every case, be found to contain more or fewer bacteria immediately after milking. But the cleanliness of milking has a very great influence on the number of bacteria found in the milk, and has also a very important influence on the nature or character of these organisms.

It will now be necessary for me to amplify and illustrate these two statements in greater detail. Let me direct your attention to Table 1, which gives in tabular form the results of examination of milk which was milked with varying grades of cleanliness.

A. Thus the average of samples A is 4,300 bacteria per c. c. (16 drops). These samples were taken from herds where all reasonable precautions were taken to insure cleanliness. Thus, the cows were brushed, the udders wiped off just before milking, any mud, etc., being washed off, the milkers' hands were washed and dried before milking, the cows were milked in a barn free of dust, pails thoroughly clean and scalded.

B. The average of samples B is 15,500 per c. c. These were taken from cows milked in a fairly clean but dusty barn, the udder was brushed free of coarse dust. The milker's hands were not washed, but were wiped after each milking. Pails clean but not scalded.

C. The average of samples C is 30,000. These were taken from cows milked in ordinary way, i. e., cows not brushed, udders cleaned by running unwashed hands over them before beginning to milk. Pails clean but not scalded. I am indebted to Dr. Park of the New York Board of Health for these figures, which were published in Journal of Hygiene, Volume 1, page 391. My own figures, from some examinations made under like circumstances, closely approximate to these, but as Dr. Park's are based on a larger number of samples I have used his figures for the tables.

Table 1.—Number bacteria in 1 c. c. at time of milking:

A.	B.	C.
4,300	15,500	30,000

These figures show better than talking can do the difference which cleanliness makes in the average bacterial content of milk at time of milking. It is evident that the lack of cleanliness in milking means the seeding of milk with a great number of bacteria derived from outside sources, and these sources must be the dust and hairs, including the manure particles from the cow, together with the dust of the milking place and bacteria derived from straining cloths and milk utensils. The bacteria which are present in practically all milk, even when most carefully milked, are derived from the milk ducts of the cow, and are found in greatest number in the fore-milk. Generally in the ordinary healthy animal, the vast bulk of these are the common lactic acid or souring organisms, a class of bacteria desirable in both butter and cheese making. But we cannot say the same for these bacteria which get in from the stable dust and dirt from the cow's udder. Many of these are bacteria capable of setting up most undesirable changes in the milk, if the temperature conditions be favorable and their growth be not checked by the lactic acid forms present. The organisms which do get in under these conditions, are such species as produce gassy, bad-smelling milks, or which show up later by producing pinhole, gassy or foul-smelling curds and many like undesirable conditions. I think we can take it as a rule that the cleaner the milking and milk utensils, the fewer the bacteria and more likely they are to belong to the lactic acid varieties; and on the other hand the dirtier the milking the more bacteria will be found, and the lactic acid species will be mixed in more or fewer numbers with gas-forming and like undesirable forms.

It is now a well recognized fact that when milk is kept at a low temperature, being cooled down shortly after milking,

it keeps a long time. It is not so well recognized a fact that the cleanlier the milk is the longer it will keep good at this temperature. Dairymen who supply milk to cities recognize this fact. Perhaps I should modify my statement and say that some at least do. For town or city delivery the producer usually cools his milk as soon as possible after milking, and keeps it at a low temperature until he can deliver it. Now I claim, and rightly as I think, that the cheese and butter makers have as good a right as the milk consumer to have a good, pure article of milk.

Next to cleanliness of milking, of milk vessels and surroundings, as bearing on the number of bacteria, stands the temperature at which the milk has been kept before delivery. Let me direct your attention to table 2, where you will find some figures given illustrating the effects of various temperatures on milk. The period chosen for the examination is 24 hours, as under laboratory conditions this is the most suitable. However, the figures would be fairly proportional, say for milk 15 to 18 hours old.

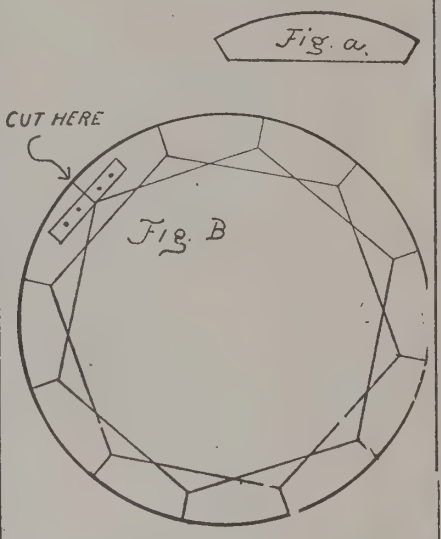
Table 2—Effects of temperature on bacterial contents A and C (Table 1) samples of milk after 24 hours, 1 c. c. milk.

	50 degs. F.	55 degs. F.	60 degs. F.	68 degs. F.	86 degs. F.	94 degs. F.
A	4,500	18,800	180,000	450,000	1,400,000,000 turning.	25 000,000,000 } sour and
C	48,000	187,000	900,000	4,0 0,000	14,400,000,000 sour.	25,000.000,000 } curdled.

It will be seen from this table that when milk is rapidly cooled and kept below 50 degrees Fahrenheit that there is very little change in first 24 hours, while as the temperature goes higher the increase becomes very noticeable until it reaches the maximum limit. These figures will show very clearly the great influence which temperature has upon bacterial development, and shows better than many lectures the influence of temperature in preserving milk and the benefit derived from the cooling of the milk. It also shows very clearly that the milk which was the cleaner to begin with, shows less bacterial development through the entire range of temperature until we reach the highest, where the development in both is so rapid that it reaches its maximum within 24 hours, and the milk becomes very sour and curdled.

Again, with regard to the kinds of bacteria found. The gas-forming species will grow quite as well if not better than the common souring germs at the higher temperature. However, no figures can be given which will definitely show the proportional increase in the number of the acid-forming, and the gas and other species in milk, as the results of analyses differ markedly in almost every instance. Of one thing I am assured, however, and that is, that other things being equal the common, pure lactic acid producing bacteria, develop better and more rapidly at the lower temperatures than do the common gas-forming varieties, so that milk properly cooled in summer is very seldom gassy milk. On the other hand, it is during the hot weather of midsummer, when the farmers do not cool their milk, that there is much trouble from gassy and foul milk, and pin-hole and gassy curds, I think that there are just as many gas-forming species in the milk during the cooler weather as in the hot season, but the acid-formers are the species which thrive best at the existing temperatures during these periods, and thus the growth of the gas-formers is checked, while the warmer the atmosphere, is the more the chances of both species developing, are equalized. I have taken the gas-formers as the type of the undesirable species whose presence and development are particularly aided by lack of cleanliness and high temperature, but I would call your attention to the fact that the hot months of the year are the periods during which nearly all the trouble is found. Of course, I am not now referring to winter dairying, which has troubles peculiar to itself.

In winter dairying, where cows are not kept very clean, the infection of the milk with undesirable bacteria is sometimes enormous. The low temperature at which the milk is kept stops bacterial growth of all kinds, and then when such milk is brought to creamery or factory, it is heated up to hot summer conditions with the result that we give the undesirable species an excellent chance to develop, and as they are usually more numerous than the common acid species, such milk is often very foul and produces a bad article of butter or cheese. I would commend these facts to the consideration of those making winter or "fodder" cheese. The buttermaker can overcome this by pasteurization and the use of a starter, but the cheesemaker has to fight the "dirt" in his milk, as so far no successful system of making cheese from pasteurized milk has been devised. Of course the cheesemaker has to depend upon the controlling influence of a good starter by which he adds vast numbers of the acid-producing species to the milk.



The points I want to impress today are simply those of greater cleanliness of milking (and all that appertains to this, i. e., cleanliness of utensils, stables and dairy shed) and greater attention to the cooling of milk. Some may say that if milk is thoroughly cooled, say to 55° Fahrenheit or thereabouts, that acidity develops very slowly and that there would be insufficient development of acid-forming bacteria for cheesemaking purposes. If this is the only difficulty to be overcome, its solution is very easy. Add a pure lactic starter and you can secure this factor, but do not use the starter simply to hasten the end of the day's work. I know the difficulties attending a wide adoption of such a method, one of the most important being the maintaining of such a pure starter at all times. I believe it has now come to the time when our instructors should preach not only the doctrine of cleanliness, but also the doctrine of cooling the milk more thoroughly. The Department of Agriculture (Dominion) have been experimenting in keeping cheese under temature conditions approximating those found in England. The experiments, from the reports received this past season have been very successful, resulting in an added value for the cheese so cured. Let us go a step further back in the process and begin more nearly at the beginning, i. e., approximate to English temperature conditions by cooling the milk more carefully. In other words apply English temperature conditions throughout, from the time of milking till the cheese is put on the market. If you like, you can substitute for English temperature conditions, our own temperature conditions early in June or the last half of September, both seasons of the year in which ordinarily the best cheese are made. I do not think it advisable to insist on too low a temperature for the cooling of the milk, but certainly for cheesemaking, 60 to 65° Fahrenheit is as high as advisable. For butter making 55 degrees Fahrenheit I would set as a limit.

Another matter which demands emphasis being placed upon it, is the danger which follows the taking back of whey in the milk cans, particularly from whey tanks that are not kept properly cleaned. Prof. Harrison has shown, and I can most emphatically back him up in his statements, that the usual cleaning which cans get does not suffice to free them from the bacteria found in the whey (usual cleaning by hot water and brush, and then rinsing with hot and cold water.) It requires steam or boiling water to thoroughly destroy the bacteria from a perfect can, and the older and more battered a can the longer the exposure to these agents is necessary Therefore it is better to avoid the danger of infecting the milk from the whey tank by not placing the whey in the milk cans.

To sum up. I think I have shown, first, that the cleaner the milking, the smaller the infection of the milk with bacteria, particularly undesirable forms. Second, that the lower the temperature at which the milk is kept, the less the bacterial development. Further, moderate temperatures, say up to 65 degrees Fahrenheit, aid mainly the normal acid-forming varieties, while temperatures above this are as suitable for the development of such species as the gas-forming varieties, if these happen to get into the milk in any numbers. These two factors of cleanliness and cooling of milk, are the factors of importance to dairymen to day, for if they are not lived up to, we can never get our cheese to come up to that produced in England even though English conditions are provided after cheese are made. The maker can only produce the best article from the best raw material, so that in this, as in everything else, one must begin at the begining, and that is with the milk producer.

Concrete Foundation for Round Silo.

ED. HOARD'S DAIRYMAN:—The following will answer the inquiry of E. J. R., Auburn, N. Y., in relation to building concrete foundation for silo, for any depth desired. Having used such a form for the purpose, it being inexpensive and easily made, I find it much better than any other I have seen used. I will not submit exact measurements for the reason that the person constructing it can easily do so without instructions.

First, let E. J. R. strike part of a circle 14 feet in diameter on a board, say 10 or 12 inches wide and about 3½ or 7 feet long for a pattern, and cut same like Fig A, and use same for pattern for making enough pieces like it to form two circles of the required size, also mark on ground or a smooth floor, a circle of size wanted, using same for making his form by laying these pieces upon his circle.

First, fit one course to make the complete circle, and then put a second course on top of that, breaking joints in center, as in fig. B, and so on to complete his circle, nailing the two courses well together with wire nails, and clinch. After this is finished, nail upon the edge of this form a board, not more than 8 or 9 inches wide. This should not be more than ¾ inch thick, so it may be easily bent, and the outside should be planed smooth. This piece should be nailed with center on edge of form, and if there be any difficulty to bend it, it may be cut across on the inside face with a saw part way through, at regular spaces, say two inches apart.

Nail several triangular pieces for stays on inside of rim, and on top of the pieces that make the form, which will serve to keep the rim true. At some point in form, say at one joint in lower course, saw through the completed form, and take out a piece about one inch wide from the flat pieces, but leave the rim whole, this is for the purpose of being able to loosen the form when necessary to move it. In order to keep in proper position when in place, use a piece of board with two pins in each end, as indicated in Fig. B. This form is so easily constructed and operated, I don't think that any person will have any trouble to make or use it. I find from using the above, it is much preferable to any thing else I have yet seen.

A Dairyman's Experience.

Aims to Develop a 400 Pound Herd.

Sometime ago I noticed in the *Review* a request for our dairy methods after your having given us some "boquets." If in any way our methods will be of any benefit to your readers we will gladly give them, but considering that all our experience in dairying dates since May 1901, it seems a presumption on our part to compare our methods with those of your readers who have been dairying for years.

In May 1901, we, my brother and I, rented the dairy of A. C. Freeman in Sacramento Co., on shares. I never saw a wilder and more vicious lot of cows. They had run with their calves for about three years, up till about four months before we took them in charge. Hired help of the kind usually available for dairy work, had been handling them and the parties were as vicious as the cows. The cows had been so badly abused that some of them would jump out of the corrals when we brought them up at nights.

We began by talking very low while we were with them, offering fruit and petting those that would allow it. The first two months these cows averaged $2 per head per month, their milk testing 4% fat. During the same months for 1902 they averaged $7.25 per head, their milk testing 5%. We kept a note of our neighbor dairymen's doings and when we saw they made mistakes we avoided them. But we owe more to the *Jersey Bulletin*, HOARD'S DAIRYMAN and the *Dairy and Produce Review* than all other sources. I nearly forgot to mention Prof. Leroy Anderson and Dr. A. R. Ward of Berkeley in the above. But to estimate the great value that these five sources of dairy information have been to us would be hard to do. To give it in print would seem an exaggeration.

It would be interesting to recite our many mistakes and experiences, but space will not permit. So I will be as brief as possible. The place which we devoted to dairying consisted of possibly 140 acres, 80 of which were sown to alfalfa and on this we had about one-fifth of a stand. The rest of the land was bottom pasture land with Canada thistles very thick on it.

In the beginning we tried soiling with alfalfa for night ration, but the cows would decrease in milk so that we drove them to the pasture at night during summer and autumn, where they might feed unmolested by heat, and the flies were not so bad. In the fall we harvested a large crop of pumpkins which we tried to feed for night ration, but it was a greater failure than soiling This proved to us that the alfalfa pasture was better than any other manner of feeding. When cold weather and the storms came we tried leaving the cows fastened in the stanchions over night but the poor things were so stiff next morning we gave it up. So we rolled our wagons and tools out in the storm and gave the cows the use of a large building devoted formerly to storing machinery. While our cows were making butter fat in a warm barn all the cows along the river were out in the storms, consuming their food energy in keeping warm.

We bred our cows to calve after the middle of July so we had the advantage of the best prices for butter, and when green feed came they gave as much milk as they would if bred in the spring and the drying up time is during hot weather and when flies are worst. We don't breed the cows sooner than three months after they calve and the heifers we let go for a longer period and no bulls are allowed to run with the cows. We find we have had wonderful success in calf getting. Not more than 10 per cent have had to be served twice. We try to dry our cows up two months before calving time, especially our heifers.

In the yield referred to by your paper we milked 20 mature cows and 18 two and three-years-olds (not sixty as stated) they averaged $67.72 above the cost of manufacturing butter, making butter fat 294½ pounds, (which does not include over churn) and 5,885 pounds milk. In this is not counted 3½ gallons of milk and one pound of butter used daily on the ranch. Our best cow gave over 11,000 pounds of milk, testing an average of 4 per cent butter fat.

During 1902 as soon as the weather would permit, we milked outside; having made mangers in our corral, we fed hay so the cows might eat while they were milked. We milked exactly on time each cow in her turn and milked till they would not give another drop. The cows were given water fresh from the well and it was a pleasure to see them supping the cool water. In the late summer we had about one and one-half acres of Bartlett pears which we fed and they seemed to be excellent feed, as the cows improved in milk when they were fed the pears. We fed our young heifers bran for a short while after calving. One of these heifers calved July 16, 1902, and in four days after calving tested 4.8; one month after tested 5.8 and two months later tested 6.4 and is now giving an average of 22 pounds of milk a day testing 6.4.

The foundation of this herd was Durham cows, having been bred to the Jersey for seventeen years. The choicest of these cows were sold to S. F. dairymen about five years ago.

We have the special-purpose dairy type of cows and they have paid in butter more than our neighbors have in butter and calves. Our steer calves sold for $16 per head when they were from six to nine months old, and we were offered $22.50 per head for all the heifers of the same age. (We have since bought the best of Mr. Freeman's herd). With the foundation we have and through the kindness of Judge Shields in placing his great bull and his registered cows with us, I see no good reason why we cannot have a herd that will average 400 pounds of butter per cow after a few years of judicious breeding and care. We could have done better with the same cows, having seen our many mistakes. Our great secret is: We love our cows and they love us.—CLAUD TRIBBLE, in *Dairy and Produce Review*.

Suggestions for the N. C. B. A. Meeting Wanted.

ED. HOARD'S DAIRYMAN:—The Executive Committee earnestly requests butter makers and others interested in the welfare of the National Creamery Butter Makers' Association to send in suggestions regarding the next annual convention, and subjects they think need discussion at the sessions. The committee is desirous of preparing a program that will be both interesting and instructive and invites the co-operation of all.

Address communications to the Secretary at Elgin, Ill. E. SUDENDORF,
Sec'y N. C. B. Ass'n.

"ADVERTISEMENT."

THAT'S THE TIME

When Proper Food is Necessary.

Proper food is never more necessary than when recovering from a wasting sickness, when over-eating would be fatal and yet the body needs nourishment and plenty of it.

At this time the condensed food Grape-Nuts is shown to be one's most powerful friend. Four teaspoonfuls of Grape-Nuts and cream will sustain a healthy man for half a day and a less quantity in warm milk will build up the convalescent wonderfully. No stomach is too weak to digest and relish Grape-Nuts. "I was taken sick with Typhoid fever and everyone who has had this disease knows how weak and lifeless a person feels when beginning to recuperate.

"I had to be very careful about my diet and could eat only very light foods. These did not seem to nourish me and instead of getting better every day I was just at a standstill and everyone began to fear a relapse. One day while lying in bed very much discouraged my sister, who was reading to me from the paper, read an article about Grape-Nuts and we decided to send for a package.

"From the very first meal of Grape-Nuts I began to improve, strength came in bounds and leaps with the result that I was soon out of bed; my change for the better seemed simply marvelous. My mind is clear and strong and my body sturdy. I am now entirely recovered." Name given by Postum Co., Battle Creek, Mich.

There is a reason.

A dessert that helps the body, that's the thing! Any number of them in the little receipt book in each package of Grape-Nuts.

Empire Empire

Eight Years Fifteen Cows

1895 1896 1897 1898 1899 1900 1901 1902

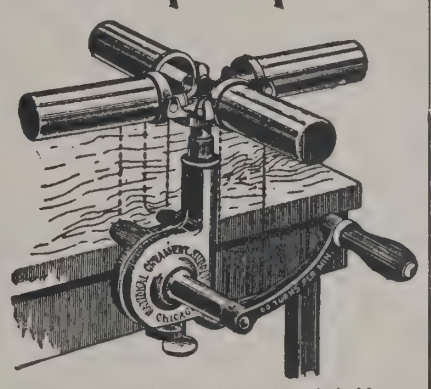
The Empire Way Makes Cows Pay.

How's This For a Record?

Emporia, Kans., Jan. 2nd, 1903,
Empire Cream Separator Co.,
Bloomfield, N. J.

Dear Sirs: Have used one of your **Empire** Cream Separators for the past eight years, during which time I have been milking at all times from twelve to fifteen cows. The cost for repairs in the eight years has been only seventy-five cents. I have had experience with other separators but consider the **Empire** superior to any other, as it never caused me any bother. It is easy to clean and has proven very durable. It does good work at all times.

L. H. VAHSHOLTZ,
Rural Route No. 4.



The Empire Cream Separator turns more easily, is more easily cleaned, does better work, and costs less for repairs than any other, because it is the **simplest separator made.** Don't buy a separator until you have investigated the merits of the Empire.

Send for our new book on Making Milch Cows Pay.

Empire Cream Separator Company,
Bloomfield, N. J.
Western Office—FISHER BUILDING, CHICAGO.

Eight Years 75 cents for Repairs Fifteen Cows

NATIONAL
Babcock Milk Tester

Dotted Lines show position of bottle holders when not in motion.

Has enclosed cut gears.
Swinging bottle-holders.
Runs without jar.
As well made as a cream separator.
Best tester for dairymen ever made.

The weight of machine when boxed, approximately 11 lbs.

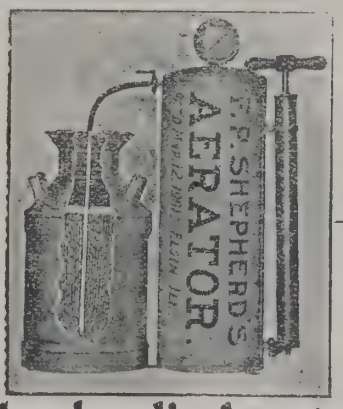
DOES YOUR DAIRY PAY?

It costs no more to feed a profitable than an unprofitable cow.

NET PRICES:

No. 1,—2 bottle, complete for testing milk.... each $4 00
No. 2,—4 bottle, complete for testing milk.... each 5 00
No. 3,—2 bottle, complete for testing cream and milk, each 4 50
No. 4,—4 bottle, complete for testing cream and milk, each 5 50

Prices include full directions for making test, bottle of acid, test bottle brush, acid measure, dipette and test bottles.



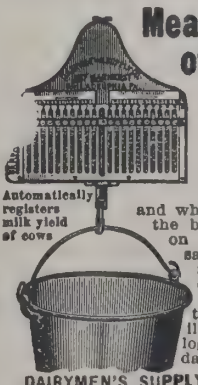
We are the great Dairy Supply House of the West. We carry an immense stock of all kinds of Butter and Cheese Making Apparatus and Supplies. Write for catalogues and circulars.

National Creamery Supply Co.,
450-458 Illinois St.,
CHICAGO, U. S. A.

Banner Lye

One can make ten pounds of the best hard soap or twenty gallons of soft soap without boiling or large kettles.

$3 a Day Sure Send us your address and we will show you how to make $3 a day absolutely sure; we furnish the work and teach you free, you work in the locality where you live. Send us your address and we will explain the business fully, remember we guarantee a clear profit of $3 for every day's work, absolutely sure. Write at once. ROYAL MANUFACTURING CO., Box 855, Detroit, Mich.



Shepherd's Aerator

is most simple, most effective, least trouble. While you go on milking millions of air globules from the charged tank are passing up through the milk, driving out all animal heat and foreign odors. Works in shipping can. No other vessel to clean. **King among Aerators.** All dairymen prize it. Write for descriptive circular.

F. P. SHEPHERD & CO., Elgin, Ill.

Measure the Milk of each Cow

With the **Automatic Milk Scale** you can keep an accurate record of the yield of each cow, and remove the unprofitable ones from the dairy. Each button on scale arm corresponds to number of cow and when pail of milk is weighed the button registers the weight on score card. Big money saver and money maker for farmers and dairymen. Send for testimonials and illustrated catalogue of **Bestov** dairy supplies.

TRADE MARK BESTOV

DAIRYMEN'S SUPPLY CO., Philadelphia, Pa.

Our New Patent

and Great sales are the talk of all who know of them. A fortune has been made by the patentee and the farmer in a short time. For seven months the sales were over $350 00 per day. Something good can't be gotten for nothing. By putting $500.00 and upwards into this business it will be the best paying investment we know of. Farmers using the machine say that they would not do without it for two, three, and ten times the price. Common farmer can handle it in a very paying way. We can prove the great selling qualities of this machine by bank account, the bankers themselves, and the farmer. Our plan is fair and honest. Best bank references Car fare one way will be paid to responsible men whether they invest or not.

WILL IT PAY YOU TO TAKE HOARD'S DAIRYMAN?

W. H. Jenkins took a census in 1901 of 50 farmers who were patrons of the creamery in Montrose, Pa. Twenty-five of themread dairy papers; twenty-five did not. The twenty-five who did read dairy papers averaged $50.23 per cow for the year. The twenty-five who did not read averaged $32.95. Here is a difference of $17.28 per cow. Did it pay the twenty-five to read? Did it pay the other twenty-five not to read? That's not all. Those who did read averaged a profit over cost of food of $15.06 per cow. Those who did not read averaged a profit of 66 cents. Is not that dairy farmer standing greatly in his own ight who will not pay 2 cents a week for Hoard's Dairyman? These are hard facts worth thinking over.

THEY must seem to have very poor cows in Minnesota and especially in Faribault county, or there is a very serious misprint in the columns of our contemporary, the *Dairy Record*. One of the inspectors of the Minnesota State Dairy and Food Department, inspected nine creameries in Faribault county, and, according to the *Record*, found 7,150 cows supplying these nine creameries, but the aggregate pounds of milk received daily there was only 37,500—less than five and one-half pounds per cow. This, of course. is a libel on the cows of that county. The only possible explanation is that some of the creameries, if not all of them, are receiving cream as well as milk, and that possibly the pounds of cream and the pounds of milk have been aggregated in the above statement as the amount received daily.

Another inspector visited twelve creameries in Chisago county and reports 4,945 cows with an aggregate daily receipt of 85,490 pounds of milk testing 3.5 to 4.4 per cent fat.

WORTH READING.

We invite the special attention of every reader of the DAIRYMAN to the article on page 429 of this issue on the relative value of alfalfa, wheat shorts, and skim milk in connection with corn for fattening pigs. It is very rarely that so much clear, valuable truth is condensed in so small a space as can be found in this article. It gives one the true bearings of economical pig feeding in a most effectual way. Another very interesting item, full of instruction is on page 410. HOARD'S DAIRYMAN took the same ground years ago. Slowly the truth makes its way.

A GRASSHOPPER ANTIDOTE.

Mr. F. L. Washburn, State Entomologist of Minnesota, advises the farmers of that state to poison grasshoppers with paris green.

The composition recommended has been used in Northwestern Canada, where grasshoppers are usually very abundant, with great success. It is called Criddle Mixture and consists of one part paris green, two parts salt, forty parts horse manure, and water enough to make the mixture soft without being sloppy.

It is reported from Manitoba, that grasshoppers are very fond of this poisoned bait and that it attracts them from several feet distance.

THE OLEOMARGARINE SITUATION.

Not only has the new oleomargarine law been upheld by the United States court in Cincinnati, but Mr. Yerkes, Commissioner of Internal Revenue, has recently upheld his former decision that the use of palm oil, even when disguised by a mixture of cotton seed oil, is an artificial coloring under the terms of the law, and insists that one of the Chicago factories shall pay something like $30,000, we believe, additional taxes by reason of of his attempt to evade the United States Statute in regard to coloring oleomargarine. It is expected, of course, that the manufacturers will carry these cases to the Supreme Court of the United States, but meantime, the Internal Revenue Department will see to it that they do not flood the country with colored oleomargarine without paying the ten cent tax, and there is every reason to believe that the decision of the Cincinnati court and the ruling of the Commissioner will be upheld by the Supreme court.

ENSILAGE ESTIMATES.

In building a silo it is always a good plan to calculate a capacity of 4 to 5 tons per cow. That will give ensilage enough for 200 days of winter feeding and leave from one to two tons for soiling when the drouth comes in summer. If perchance the summer silage is not needed, all we have to do is to clean off the moldy ensilage from the top of it and fill in again with new on top. We believe that it is profitable to build a silo even with so small a herd as six cows, provided one can secure the filling of it in good season.

The following table may be of some service to our readers in forecasting capacity of silo, number of cows and acreage of corn needed.

No. cows.	*Estimated Consumption of Silage. Tons.*	*Size of Silo needed. Diameter and Height.*	*Acres of Corn Needed*
6	30	8x8x20	2 to 3
10	50	10x13x20	5 to 6
15	75	12x15x20	7 to 8
20	100	14x17x22	8 to 10
25	125	15x18x24	10 to 12
30	150	16x18x25	12 to 14
35	175	18x20x25	13 to 15
40	200	18x22x25	17 to 20
45	225	18x25x25	19 to 22
50	250	22x25x25	22 to 25

IS THERE TO BE A FODDER-FAMINE?

What with the excessive drought in the Eastern and Southern states and the terrible devastation wrought by floods and excessive rains in the Middle West, there is every reason to justify apprehension that the coming winter will find dairymen exposed to a fodder famine unequalled in severity by any that has preceded it. In view of this probability, it becomes every dairyman to make the most possible out of the situation. Crops that have escaped the drought and the floods should be cultivated more industriously than ever. There is ample time yet in many localities for growing abundant crops of fodder corn. Indeed, we have witnessed in this latitude wonderful success with this crop planted as late as the first of July. Planted this late, it is not expected that very much grain will be produced, or that the plant will ripen, but cut and properly cured, it makes most excellent forage. Indeed, later experience seems to demand that we reverse our opinions somewhat in regard to the corn crop. Up to within a few years, it has been an accepted tenet that the corn plant must produce an ear which must be fairly mature before the fodder was of much account, but we are learning now that what might be called corn hay, as well as sorghum hay, makes a very excellent fodder. It behooves farmers everywhere therefore to make use of every possible acre in what may be called catch crops; grow fodder corn and sorghum for hay, and millet.

WE CAN'T HELP HAVING A STANDARD.

We hope every reader of the DAIRYMAN has read the very instructive articles by A. J. Glover, of Illinois, on the differences in cows as brought out in his investigations among the herds of Illinois dairymen. Mr. Glover is doing this work for the Illinois Agricultural College and the work is done in a truthful painstaking manner. It is very suggestive, very instructive and very valuable as a guide line to every man who will read, think and learn.

On page 400 of last week's issue he compares herds "A" and "D." There is a good deal in that comparison. One thought comes to us very impressively. It is this: No matter whether we are intelligent or ignorant we can't help having a standard which we carry all the time in our minds. That standard guages our work and governs us very largely.

The owner of herd "A" had his standard. It was founded very largely on ignorance of cows, but nevertheless it was a standard and governed all his actions towards his herd.

Note what Mr. Glover says about him. The man confessed: "I never dreamed that such differences existed between cows." Now that was ignorance, nothing but ignorance. He had had all the chance in the world to make himself intelligent on this subject.

Lots of sound reading matter lay all about him. But he would not read or study. All he did was just work, ignorant work, and out of that ignorance, not intelligence, he built the standard of his policy and action towards his cows.

On the other hand, the owner of herd "D," Mr. Gurler, had done all in his power to make himself intelligent on this cow question as well as other questions. He built for himself a standard out of intelligence. Not that he knows it all, for he will tell us that he is learning now faster than ever before in his life. But the standard is as intelligent as he can make it. It governs him just as the ignorant standard governs the other man. But what a difference in money, respect of his fellows, pleasure of living and doing his work, there is under Mr. Gurler's standard, as compared to what comes to the owner of herd "A."

Let us remember, always, that if we persist in despising knowledge, then ignorance will build our standard, and we shall reap as we have sown. Every man must have his standard of action. On him will depend whether it is the standard of intelligence or ignorance.

LONG KEEPING MILK.

Among city milk consumers there is a well grounded suspicion that milk that keeps sweet for more than a few hours after being received from the milkman has been dosed with preservatives. There is no doubt that judging from the past, and in many cases the present, conditions, such milk does contain preservatives in some form, and the suspicion of the city consumer is well grounded, and city milk, as a rule, deserves its poor reputation.

The conditions under which the majority of milk is produced, shipped and handled in the city trade are responsible for this, for a bulky food product that must be produced cheaply, shipped and handled cheaply that it may be sold at a low price, as is at present required, will not stand the extra care that is necessary to improve its quality without an increase in its selling price, and that in a majority of cases is not possible. But provided that an increased price could be obtained there is no reason why all milk could not be so improved in quality by increased cleanliness in production and methods of handling, that sour milk would be an unknown quantity to the city consumer, without the use of preservatives, and in cases where the producer and seller are one and the cost of production lessened by the elimination of the middleman's profits and the railroad freight, milk that is clean and therefore long keeping, can be supplied to small cities without an increase in selling price, provided the dairyman is willing to undertake the necessary trouble as to care and cleanliness.

The great trouble with the average dairyman is that he does not know or try to know or understand what cleanliness means in connection with milk. With most men there are different degrees and quality of dirt and the quality depends on personal habits or local conditions, but with milk all dirt is bad dirt, there is no gradation or degree as to its quality; it is all bad, and until dairymen have had pounded into them a just appreciation of this fact, there will be made poor butter, poor cheese and poorer city milk.

Provided that a dairyman will take the precautions to keep things clean and then make clean milk, there is no reason why city milk should not remain sweet from two to ten days, depending on the degree of cleanliness that is used in producing it and the care that is used in keeping it after it leaves his hands. But the latter part is least important as the few hours that it is in the hands of the consumer before being used, has but little effect on its quality when it is already as poor as is possible for it to be, and would have no effect if it was clean in the beginning. The mischief is done during and following milking, while it is yet warm and subject to contamination by its surroundings. It is then that dirt with its accompanying bacteria finds its way into the milk and once there, there is no way of removing it.

Milk that contains no bacteria will not sour, and so long as bacteria are not allowed to get into the milk, it will stay sweet. Thus the question of long keeping sweet milk is entirely one of cleanliness. It is impossible to exclude all bacteria from milk by any method of cleanliness that is practical to the dairyman, but it is possible to produce milk with a few thousands in place of the many millions of bacteria that are usually found in it.

Any dairyman can produce such milk if he will pay attention to the fundamental rules of clean stables, cows and milk utensils and his success will be entirely one of degree and in proportion to his degree of cleanliness. Milk produced under such conditions will keep any where from two days to a week and is a more wholesome food, more palatable and better in every way.

BACTERIA.

We trust no reader of HOARD'S DAIRYMAN will be deterred, either by its title or length, from reading the article, in another place in this issue, on this subject as related to dairying, by Prof. Connell of the Ontario Agricultural College. Bacteriology is relatively a new science, but it is one which touches mankind at all points and should be understood in some measure by all people. It is not to be expected that any considerable number of people will become expert bacteriologists, any more than they are expected to become expert analytical chemists, but that is no reason why we should not become comparatively well informed on these subjects, or at least sufficiently informed on them to understand and ap-

preciate the conclusions reached by the experts in either science.

Bacteriology and chemistry are of especial interest and importance to the dairymen. The chemist analyzes our feed stuffs and aids us very materially in determining which to select and why to choose them. Bacteriology informs us in regard to those matters which control the growth of some and decay of all substances. It has taught us how and why the leguminous crops are soil renovators and of such prime importance as feeds. It is, however, in the matter of milk and its products that bacteriology assumes its highest importance as a handmaid in dairying. It tells us why milk sours and the conditions which favor or prevent souring. It tells us why milk sometimes has offensive odors and will not make good butter or good cheese. It also tells us why sometimes milk becomes practically a poison to infants and adults as well. In other words, the presence or absence of certain species of bacteria determines the character of milk.

It will help very much to an understanding of Prof. Connell's paper for the reader to remember that bacteria are not animals or bugs, but are in fact the very lowest, microscopical forms of vegetation that grow, develop and multiply under very similar conditions that grains and grass and weeds grow, develop and multiply in our fields. For example, Prof. Connell speaks about controlling the development of undesirable bacteria in milk by seeding it with the lactic acid developing species, very much as we speak about corn and oats and other crops of grain getting the start of the weeds and keeping them down.

Pasteurization is simply applying enough heat to kill the bacteria which may be present, just as boiling, or hot, water, if poured upon plants, will kill them, The degree of heat used in pasteurization is not sufficient, however, to kill the spores or seeds of many species of bacteria, just as water hot enough to kill a living plant, will not kill the seeds of that plant.

Sterilization differs from pasteurization simply in the degree of heat applied and its duration. Thus, when the surgeon talks about sterilizing his implements and the dairy bacteriologist about sterilizing the vessels which come in contact with milk, they mean simply that they have been subjected either to such a degree of heat, or have been treated with some antiseptic to a degree which not only kills all the living bacteria, but also effectually destroys the germinating power of the spores or seeds. Dairy cleanliness implies not only removing all visible dirt, as that word is commonly understood, but in applying such a degree of heat to the utensils as will completely exterminate bacteria and bacterial spores.

A farmer easily understands what will happen if he allows a single burdock-burr to grow in his soil. Nothing short of eternal vigilance will prevent the multiplication and spread of this weed. It is much the same with bacteria, for example, in the milk can, except that in the case of the burdock weed, the multiplication is comparatively very slow, whereas with the bacterium in the milk can, the growth and development is astonishingly rapid and increases in a geometrical ratio.

Looked at from this point of view, what Prof. Connell says about temperatures favorable and unfavorable to the growth of bacteria, becomes perfectly plain and simple. Certain kinds of weeds will thrive in the soil of our fields at a comparatively low temperature, others can make no growth whatever until the warm weather sets in, and then they shoot ahead marvelously. Most fortunately for us, in this respect as in so many other respects, nature has so ordered matters that with care and prudence and vigilance, we can keep down the weeds in our fields to such an extent that they will not seriously interfere with our regular crops, and by the exercise of the same virtues we can produce and hold and transport milk without serious impairment from bacteria.

These problems should receive at this time the very serious consideration and attention of those dairymen who are delivering cream to factories from hand separators. If they will take proper precautions in milking and, after that, take proper care to keep the cream cool and have it transported to the factory often enough and with proper precautions against the weather, the farm separator plan of running a creamery will take precedence over all other methods.

Again, we urge every reader to give Prof. Connell's paper not mere cursory reading but careful study.

THE COOPER SALE OF JERSEYS.

The great Cooper sale of Jerseys at Linden Grove, Penn., came off as advertised, May 30th, and resulted in the sale of 107 animals at an average price of $292 each. The bull Forfarshire topped the sale at only $1,750, whereas, last year $7,500 was paid for Flying Fox, an animal in no way superior probably to Forfarshire. This price is also some $500 less than Mr. Cooper paid a few days ago for Golden Fern's Lad; all of which goes to show that the top prices obtained for the so-called "plums" at auction sales depend quite as much upon the spirit of the purchaser as the merits of the animals themselves. Forfarshire went to Filston Farms, Glencoe, Md. Filston Farms is primarily a dairying establishment, furnishing high grade milk to the citizens of Baltimore, but this purchase of Forfarshire and eight other animals at the Cooper sale indicates that the management there intends that for the future, as for several years in the past, Filston Farms is not to be outdone in the matter of breeding high-class producing Jerseys.

The highest priced cow was Golden Lad's Blue Bell, purchased for Biltmore Farms at $1,725. Mr. Thomas F. Lawson of Mass., who paid $7,500 last year for Flying Fox, paid $1,050 for Flying Fox's Foxhall, and Dr. C. E. Still of Missouri, came in second on females, paying $1,400 for Flying Fox's Brown Beauty.

In this sale of 107 head, only five animals brought $1,000 or more. Eight animals sold between $500 and $1,000 and twenty-three sold for $100 or less. These last, of course, were all youngsters, but none the less, they justify our contention that it would be a profitable practice for more plain dairymen to be represented at these great auction sales, where there is always opportunity to secure the very choicest breeding at prices merely nominal compared with the sums realized for the more noted and mature specimens.

INJURED UDDERS AND TEATS.

H. E. Cook, one of the noted dairymen of New York, states in the *Rural New Yorker* that one of the serious problems that confronts every cow milker " is the loss of teats and udder trouble." He says farther:

"This question in an institute "question box" is second only to feeding. In our own experience it annually foots up a heavy loss. No one cause seems responsible. A variety of mistakes and accidents are effectiev, some of them I must acknowledge due to ignorance, lack of care and to that class of happenings that could have been prevented. My hindsight is good and foresight poor, hence many of these mistakes. Poor milking or harsh milking, a lack of perfect uniformity in feeding, a disposition to feed high when prices are high, excessive use of rich nitrogenous grains, cows out in a cold day or cold rains are all responsible, and a cause more prolofic than all these, operating with them, is an organic weakness of the udder. Good cows are those with large udder capacity. These are the animals from which we raise calves and so intensify the weakness. All of these things look the every day business farmer in the face, and must be met"

We wonder if Bro. Cook does not use the old-fashioned stanchion? We see he does not enumerate that as one of the causes, yet in our experience we have found it the most prolific of all causes in the creation of injury to teats and udders.

Since we have discarded the stanchion and that is over twelve years, we have not had a single case of injured teat or loss of quarter in the udder. Mr. Cook says that in his own experience "it annually foots up a heavy loss."

We would suggest that he try the Model stall or some of the other most excellent substitutes for the rigid stanchion.

So far as we can determine, the only reason on earth why farmers use the stanchion is because it is handy for the farmer. No particular thought is taken as to its effect on the cow. She can't talk and the owner will not take pains to look into the matter.

We are confident also that the cold cement floor will prove a very prolific source of injury to udders unless especial pains is taken to floor it over and thus prevent the udder from coming in contact with the cement.

There are many physiological laws connected with the handling of cows, and it is well to handle the cow in obedience to them.

Mr. Stevens' Home Burned.

Valuable Herd Records Lost.

ED. HOARD'S DAIRYMAN:—I regret to tell you that Elmwood Cottage burned May 19th. Fire caught in roof at 8:30 a. m., a high wind blowing at the time, and in less than 20 minutes the roof fell in. No accidents, all well. We saved contents of 3 rooms. My file of monthly creamery statements was rescued, but a regretable loss is a file of 8 or 9 volumes of HOARD'S DAIRYMAN beginning with the volume containing a complete report of the memorable Battle of the Dairy Breeds at Chicago in '93, giving a good history of the progress of the dairy industry during a period of great improvements in methods of handling dairy products, and caring for dairy cows, also in producing or breeding a better class of dairy cows. Three-hundred- pounds- of- butter- per- year cows, while entirely too few, seem to be more numerous than they were ten years ago. My file of monthly milk sheets containing the record of the milkings of each cow for a period of ten years, was burned. These records consigned cows to the butcher, or retained them in the herd, also changed their relative position in the herd and show a quality in a dairy cow that is not found by measuring with a tape line or weighing the cows on a stock scale. A. M. STEVENS.

Ellensburg, Wash.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

Alsike Clover for Seed.

Would you advise threshing alsike clover for the seed and then feeding the threshed hay to cows, for winter feed? What is the approximate value of it for feed?

We have 40 acres of this clover.

You may continue sending me your paper and I will renew soon.

Kendalls, Wis. Mrs. S. M. C.

Clover seed of any variety is a profitable crop even with a medium yield. A profitable yield is seldom or never secured with the first crop. This should be cut for hay and the second crop, if any, reserved for seed. The ripened, weather-beaten clover straw or haulm has comparatively little feeding value. All kinds of stock will pick it over more or less and derive some benefit, but we could not advise depending on it as a substitute for good hay, for feeding milch cows.

From Idaho.

Mr. M. G., of Woodland, Idaho, in sending us a continuation of his subscription at short rates, contrary to what is a common report in these parts, writes that "dollars do not grow on the bushes in Idaho." However, he is considerably interested in the cow business, although at present he has only five head of cattle and one of them a steer; but one of his neighbors, a little further advanced in dairy practice, has a square silo with round corners and "a Jersey bull of the vest pocket size."

Under these conditions our correspondent requests some suggestions for arranging a barn for ten or twelve cows, four horses, silo, small granary, etc., etc. Size of barn to be 24×36, with 16-foot shed on south side and west end.

We do not quite understand what our correspondent means by the shed on the south side and west end, whether it is to be open or closed, and in the latter event, used for stabling cows and horses. Open sheds are not so much in demand by dairymen in recent years as they were by our fathers and grand-fathers, for experience has taught us that the better place for the dairy cow, when the weather is such that she cannot remain out of doors, is in the closed, well-ventilated stable. If, therefore, our friend's suggestion for the shed is to have it enclosed and serve for a stable, we suggest that it would be more economical and better in the long run to make a full sized barn and dispense with low sheds. In planning a stable, we like to allow three and one-half feet space for each cow and five for each horse. Twelve cows will, therefore, require forty lineal feet for standing room and four horses twenty feet. We prefer building the silo separate from the barn and connected with it by a hall or alley from six to eight feet wide and as long as may be necessary. We suggest, therefore, that our correspondent plan to build a barn about fifty feet long and thirty-four feet wide, that he arrange to stable his cows on one side of this barn and devote the other to horses, grain-bins, granary and box-stalls, or better yet, use the upper floor for granary, reserving all of the space below for stabling, storage and passage-ways.

As to Cement for Stable Floors.

Being about to build new stables for dairy herd, and not being entirely satisfied whether to use wood or concrete for surface of stall platform, advice is requested on two points.

Why not make front half of platform with two-inch plank surface, and rear half, concrete, being careful to have roughened surface to hold bedding? In New England, bedding is very scarce, and we are quite certain not to have enough so that knees can be properly protected from contact with concrete, but will try to have reasonable amount to cover rear half.

What is proper length of platform for average Guernsey cows, pure bred or grades? We plan to use the Bidwell stall, or equivalent.

NUTWOOD FARMS.

New Market, New Hampshire.

See the answer to C. H. H., Mount Joy, Pa., in this issue. From what is said there, it follows that we would especially object to the use of concrete as suggested in the above inquiry. If there is any part of the anatomy of a cow which needs exceptional protection, it is the udder. This is one reason why cows should not be permitted to lie out in cold and frosty nights, or be subjected to cold rains and driving storms. The udder is a very sensitive organ, and, if the concrete floor is used, a double supply of bedding should be interposed between such a floor and the udder. Several instances have come to our knowledge recently, where parties using and heretofore commending concrete floors have found it expedient to cover the standing platform with boards or plank.

The average Guernsey cow as regards length of body is an uncertain quantity. A platform four and one-half feet wide would probably accomodate the greater proportion of such cows, but undoubtedly, some might require as much as five feet, and, for others, four feet would suffice. A very good way to fashion a platform, is to make it four feet wide at one end and five at the other.

Plank or Concrete for Stable Floor.

Which would you prefer, plank or concrete floor for cow stable? My stable which at present has a ground floor must be repaired and I would like something better.

It is less than a year that I started taking the DAIRYMAN, but am well pleased with it. C.H.H.

Mount Joy, Pa.

The DAIRYMAN has never advocated, and its Editors have never practiced, the use of concrete floors as a standing platform for cows or stock of any kind. Such a floor has some advantages from a sanitary point of view, but in our opinion, these are outweighed by the disadvantages. Concrete or stone of any kind is a very excellent conductor of heat, as one can easily determine by placing his hand upon a stone, or standing bare footed upon a concrete floor. Such a floor absorbs the heat from the body, unless very thoroughly and completely protected by an abundance of bedding. Cement is all right for gutters, drive ways and mangers, but for drive ways and walks should be left rough, that is, should not be troweled down smooth.

Jerseys and Guernseys

Will you be kind enough to inform me what is the difference between the Jersey and Guernsey breeds? Which breed holds the highest record for butter fat? I have six of what I call grade Jersey and some people say they are Guernseys. Hope I am not asking too much for a new subscriber. J. W.
Provo City, Utah.

It is a somewhat difficult matter to express in words just what are the precise differences between the Jersey and Guernsey breeds of cattle. Both breeds are especially noted for giving moderate amounts of milk containing more than the average per cent of butter fat, and consequently, relatively smaller proportions of other milk solids. This circumstance tends to make them relatively more economical producers of butter than the cows of breeds especially noted for large flow of milk containing smaller percentages of butter fat. As a rule, the Guernseys average a trifle larger than the Jerseys and are of a more quiet disposition. There is less variety of color among them than among the Jerseys. They are universally of some shade of fawn with more or less white markings, and more frequently than otherwise, have a white shield in the forehead. With very rare exceptions, they have buff noses. The Jersey on the other hand, almost invariably, has a black nose encircled with a ring of light or mealy colored hair. In color they vary from almost a pure black through all the gradations to a very light fawn, and quite frequently, developing into light squirrel gray. They are also very often of broken color, white and black, or white and fawn. This lack of uniformity in color has been the cause of much regret among some Jersey breeders, and not many years ago, there was a sort of a crusade against the broken colored animals, and even to this day, the solid colored animals find the readiest sale among average buyers. The better informed Jersey breeders and the better informed Jersey dairymen pay little or no attention however to this matter of color, but value an animal for its dairy potency.

It is impossible to say which breed holds the highest record for butter fat, as so few of the so-called records have been made under similar conditions and supervised and authenticated under similar rules and regulations. There are so-called records for cows of both breeds that challenge credulity. At the World's Fair in Chicago, the average test for Guernsey milk was 4.285+%; for Jersey milk, 4.81+%. At the Pan-American Exposition in Buffalo, Guernsey milk averaged 4.60%, and Jersey milk, 4.58%.

Siloing Small Lot of Alfalfa.

I have an acre of alfalfa, medium heavy growth, and unless the weather changes it will be impossible to cure it (it is just beginning to blossom.) I also have a small silo, 10 by 20 ft. in which there is about 10 ft. of silage. Would it be possible to ensilo this small amount of alfalfa, or had I better wait a little and run my chances in curing it for hay. I am afraid this small amount would not pack sufficiently to keep well. M. L. S.
Kankakee, Ill.

We do not feel justified in advising this inquirer to attempt to preserve so small a first crop of alfalfa in the silo. We cannot say that it might not be fairly successful, but on the other hand, like the inquirer himself, we have very serious doubts whether it would pack sufficiently to insure good keeping unless pretty heavily weighted or very thoroughly tramped and then securely covered.

Jersey Herd Book Register.

I have recently purchased a herd of Jerseys and wish to know if there is such an article as a herd book, similar to the year book for horses?

Would you consider a bull by Recorder 29239, dam Columbiana, well bred for service in a milk herd? H. E. K.
Waupun, Wis.

Just what the "Year Book for Horses" may be, we are not advised, but if our inquirer has reference to books of registry or pedigrees for the different breeds of cattle, his inquiry may be answered in the affirmative. The American Jersey Cattle Club, J. J. Hemingway, Secretary, No. 8, West 17th St., New York City, publishes the official register for Jersey cattle, and can furnish copies of recent volumes. Full sets are difficult to obtain.

The bull referred to is of excellent breeding and fit for use in any herd.

Alfalfa Silage for Colorado.

Am very much interested in silage and believe it will make this country a good dairying country. We raise abundance of alfalfa, and that and corn silage I believe will make dairying pay here. I would like to know more about silos. Does not alfalfa silage when put in silo before blossoming, when fed to cows wet, bloat them? We have a great deal of trouble here with bloat, when we feed half matured alfalfa, if it gets wet. There is no silo in this part of the country, do you think it would pay here to have them? W. E. C.
Broomfield, Colorado.

We are unable to answer the specific questions submitted by this inquirer, as we have had neither experience nor reports from others along this line. On general principles, we should say there need be but little fear on this score as the feeder has the matter under personal control at all times. If any of our readers can throw any light on this topic, we should be very glad to hear from them. Meantime we may say that alfalfa has been very successfully siloed for many years, especially in California, and unless there is an early change in the weather, promising us a cessation of the frequent showers and heavy rains, which have visited this section of the country so frequently the last few weeks the editors will feel compelled to put their first crop of alfalfa into silos.

Belt or Turbine Separator.

For a dairy of 20 to 25 cows, which would be the best to buy a separator, run by steam, or by belt power as I now have a gasoline engine, and expect to churn my own butter?
Bryan, Ohio. H. J. N.

As the writer has a garoline engine and would find it necessarv to put in a steam boiler to run a turbine separator it will probably be better under the conditions to buy a belt separator as it can be run by his gasoline engine.

Storing Cut Hay.

As we like to feed cut hay to our cattle in winter we thought that if hay could be cut as it is brought from the field it would save one handling. As we have never tried this method, or know of any one else who has, we wonder whether or not you had ever heard of such a thing being tried and if so, with what success?
Delaware, MIDDLETOWN FARMS.

We have never tried this method of storing hay nor do we know of anyone who has, but on general principles, we can see no good reason why it might not be successful. It is not an uncommon thing to store oats in this way and it is said to be a sure preventive against mice. Hay cut in this manner would not pack as closely as when put into the mow full length.

Rearing Calves on Skim Milk.

Find enclosed 5 cents in stamps, for which, send me a milk sheet, for 10 cows. I am a new student in your class. and I would like to know what is the objection to turning calves on grass, if I spray to keep off flies? Would you advise feeding oil meal with skim milk to calves, how do you feed it, and how much? Thanks to you, I am keeping a record of the performance of each cow.
Shinglehouse, Pa. E. H.

There is no objection to turning calves on grass, provided, they are not only protected from flies but have opportunity to get out of the hot, blazing sun of mid-summer. Unless there is natural shade in pastures, sheds should be erected under which they can get away from the scorching summer heat.

Oil meal makes a very good addition to skim milk for calves, but it is not quite as good, in our judgment, as ground flax seed and no better, at least, than germ oil meal. At first, the oil meal and the flax seed, should be thoroughly scalded before mixing with the milk. For the young calf a small teaspoonful is all sufficient. As the calf grows

"ADVERTISEMENT."

LEARNING THINGS.

We Are All in the Apprentice Class.

When a simple change of diet brings back health and happiness the story is briefly told. A lady of Springfield, Ill., says: "After being afflicted for years with nervousness and heart trouble, I received a shock four years ago that left me in such a condition that my life was despared of. I could get no relief from doctors nor from the numberless heart and nerve medicines I tried because I didn't know that the coffee was daily putting me back more than the doctors could put me ahead.

"Finally at the request of a friend I left off coffee and began the use of Postum and against my convictions I gradually improved in health until for the past 6 or 8 months I have been entirely free from nervousness and those terrible sinking, weakening spells of heart trouble.

"My troubles all came from the use of coffee which I had drunk from childhood and yet they disappeared when I quit coffee and took up the use of Postum." Name given by Postum Co., Battle Creek, Mich.

Many people marvel at the effects of leaving off coffee and drinking Postum but there is nothing marvelous about it—only common sense.

Coffee is a destroyer—Postum is a rebuilder. That's the reason.

There are many reasons why the Improved

U. S. SEPARATOR IS THE ONE TO BUY

BELOW ARE A FEW OF THEM:

THE U. S.

Costs no more than inferior machines
Gets More Cream out of the Milk
Is less expensive to operate
Increases the quantity
Improves the quality
Will wear longer
Soon pays for itself
Has its gears enclosed
Bowl has few parts to wash
Has simple self-emptying Bowl
Has many other points of superiority
More fully described in our catalogues
which are free for the asking, all making

The U. S. Separator the Standard Separator of the World

For Western customers, we transfer our separators from Chicago, LaCrosse, Minneapolis, Sioux City and Omaha. Address all letters to Bellows Falls, Vt.

older and larger, this may be gradually increased until, at four or six months, the amount may be a full tablespoonful twice a day.

Clean Milk for City Use.

Just at the present time we seem to be on the eve of a revolution in the methods that are being used in handling the milk supply of cities. The authorities are discovering that there is a direct relation between unclean milk and the city health. The only trouble in this crusade is that the producer is being held responsible almost entirely for the quality of the milk. He is, no doubt, to blame to a large degree, but the methods of transportation and handling in the city should certainly come in for their share of the trouble and not put the whole burden on the shoulders of the dairyman. The following gives the view of the subject from the viewpoint of the city milk inspector:

In many of the great cities of this country the milk supply is closely connected with the health and life of the people. This is especially true of the babies in great cities like Chicago. Recently the milkmen of that city have put into force a rule of once a day deliveries. As a result, disease and death have come to many children, as much of the milk is delivered too sour to be used, so the health department claims. Of course, if the milk were clean and cleanly handled it would keep for more than twenty-four hours. But the milk is in such poor condition that it will keep for but a few hours in warm weather. The Board of Health warns the public that the dirty milkman is more dangerous than the dishonest one. An official of the Board of Health said: "The problem is the most serious the department has faced in years. It is a matter of life and death. It is practically impossible to keep milk for twenty-four hours in the congested districts, and it is in these districts that the greatest infant mortality results. The people there seldom are able to purchase ice. We believe that the milk drivers will see the dangers of the situation and give the problem serious consideration."

According to the department's statistics, close milk inspection during the last six years has brought a decided improvement in the milk supply of the city. During the previous six years, before stringent methods were enforced, there had been 66,003 deaths of children under 5 years of age in the city. During the six years now closing there have been but 51,046 such deaths. The under-5-years population, according to the federal census, increased 30 per cent between 1890 and 1900. So that on this basis, instead of 51,046 deaths in the second six-year period there would have been, had the earlier death rate continued, 85,083 deaths.

Sour milk is declared to be the cause of the increased death rate recently among babies. One of the health commissioners of Chicago asserts that the increased death rate is due to intestinal diseases caused by the fermentation set up by the attempt to digest sour milk. Chief Milk Inspector T. F. Grady of Chicago says: "Germs thrive wonderfully in the milk detained by the flakes of rust left after the can has been washed. In this way the supply for a whole neighborhood is often polluted, the children being the greatest sufferers. I have devised a red label which is to be pasted tightly on every rusty milk can coming into Chicago. The can will go back to the farmer and his name be retained. If that can ever comes back it will be smashed and the milk in it poured out, as well as any other milk that farmer sends in. By keeping his name we can tell who uses rusty cans and we shall condemn his whole supply for fear of missing the rusty can. The consequences are too grave to be overlooked. We intend also to post a circular on all milk platforms warning dealers that they must sterilize their cans before sending milk in them to Chicago. Sour milk is very common. It might be supposed that formalin would be used to counteract the tendency to sour, but careful tests have revealed none."

The war for clean dairy products should go on till we have not only pure butter and cheese, but pure and clean milk delivered to our cities.—*Farmers' Review.*

A Silo for a Sixty-five Acre Farm.

ED. HOARD'S DAIRYMAN:—I am thinking of building a silo and would like to know how large a one I need on a sixty-five acre farm, all tillable land. Am keeping twelve cows at present. Would like to known if by building a silo I could make enough to pay to keep a hired man the year round.

I enclose cut of a silo, but think it is most too expensive. Could I build a cheaper one and have it answer the same purpose. I can buy good hemlock lumber at $14 per thousand and select 2×4's for $15. Silo could be built eight feet in the ground. AN OLD SUBSCRIBER.

Omro, Wis.

It is not number of acres but number of animals to be fed which determines the proper size of silo. Sixty-five acres of tillable land about Omro, Wis., can easily be made to support forty cows and other stock in proportion. As stated in a recent issue of the DAIRYMAN, a very good rule for estimating the required size of a silo is to allow one cubic foot of space per day for each animal to be fed. Thus, for twenty cows to be fed two hundred days in the year, one would need to provide four thousand cubic feet of silo space. For this number of cows, we should advise building a silo fifteen to sixteen feet in diameter and twenty-five to thirty feet deep.

The style of silo shown in the cut and descriptions accompanying this inquiry, can be highly commended, but it is also true that a very serviceable and fairly durable silo can be made at much less cost, and it may be either circular, or rectangular with the cut off corners, as so often explained and shown by illustrations in the DAIRYMAN.

Tarring Inside of Silo.

ED. HOARD'S DAIRYMAN:—I propose to build a silo with sixteen sides, double boarded inside with two thicknesses of inch maple and beech with damp proof paper between the boards; the silo to be 6 wide, 32 feet high. What I wish to know is, will it be necessary to tar the inside lining of boards? It would seem a very disagreeable task to handle the boards fresh tarred.

The silo will be in the barn which has a basement. I can drive into the barn when the loaded wagon will be one-half way to top of silo. So with twice pitching the silage, we can throw the silage into the top of silo. I have experimented with a square silo 6 feet wide by eight feet high, and the silage kept fairly good, one thickness of maple boards, without paper, and last summer I lined this square silo with common tar paper and sprinkled the silage as put in, and had very little spoiled silage. This 6×8 silo furnished enough for my three cows all winter but the silage next the tar paper smelled strong of the tar.

I have read about others painting inside of silos with tar which I suppose would not be likely to ever get dry inside of a silo.

My cows ate the silage which smelled of tar as I could not well separate it from the other but I had rather they do not have to eat tar silage. How long do you think the inside lining of proposed 32 ft. silo will last without tar? S. E. R.

Pentwater, Mich.

It was quite the custom a few years ago to paint the inside of silos, and for this purpose gas tar thinned with gasoline was used. It is, however, an open question at the present time whether this practice was particularly beneficial. Present theories are that the sooner the lining of a silo can dry out after the silage is removed, the better will it be for the lumber. The lining of a silo is not such an expensive matter as to require very serious consideration. A more important matter perhaps would be the choice of paper to place between the two thicknesses of lining boards. The common tar paper is very easily and very quickly destroyed by the acids of silage and we suggest to this inquirer that he correspond with the Standard Paint Company, Department H. 100-Williams St., New York City, N. Y. The Senior Editor, acting upon the advice of Prof. King in the premises, has used the paper manufactured by this Company, both in his silo and for lining stable floors, with very great satisfaction. The present writer's experience is that pine lumber on the inside of the silo will last from eight to ten years without renewal.

Illinois Herd Records.

Report of Herd "B"

ED. HOARD'S DAIRYMAN:—This herd was composed largely of common native stock and grade Holstein cows. There were a number of fairly good dairy cows in the herd and a number of promising heifers. The cows weighed on an average about 1,050 pounds. The general health of the herd was good. A few of the cows aborted during the year and some of them had caked udders, and a few of them were sold on this account.

A number of them were disposed of so early in the test that their records are not calculated with the rest of the herd, but are given separately. On the whole it can be said that the cows received good care and were fairly well fed throughout the year.

The cows were fed from Oct. 1st to Nov. 1st, some ear corn, stalks and pasture. During the months of November and December, the cows received the following ration:

FOOD.	Lbs.	Dry matter.	Protein.	Carbohydrates.	Fat.	Cost.
						Cents.
Bran	6	5.31	.774	2.406	.204	3.4
Corn meal	6	5.35	.474	4.002	.258	6.0
Millet hay	8	7 04	.256	3.880	.080	4.0
Corn stover	10	5.95	.170	3.240	.070	2.0
Total nutrients.		23.65	1 674	13.526	.612	17.4

This ration would have been considerably better if two pounds of oil meal or gluten meal had been substituted for 3 pounds of corn meal and would have cost no more.

During the month of January and February the fresh cows received 7 pounds of bran, 4 pounds of corn meal, oat straw and corn stover *ad libitum*.

In March and April they received a ration about as follows:

FOOD.	Lbs.	Dry Matter.	Protein.	Carbohydrates.	Fat.	Cost.
						Cents.
Bran	6	5 31	.774	2.406	.204	5.4
Gluten feed	3	2.70	.699	1.521	.081	3.3
Clover hay	5	4.23	.340	1.790	.085	2.5
Corn stover	8	4.76	.136	2.592	.056	1.6
Total nutrients		15.00	1.949	8.309	.436	12.8

Oat straw *ad libitum*.

This is a very good ration. It is a balanced ration and contains enough nutrients for cows giving large flows of milk. If some succulent food such as roots or silage had been added, it would have been still better.

In May the fresh, cows or the ones giving the most milk, received the following ration:

FOOD.	Lbs.	Dry Matter.	Protein.	Carbohydrates.	Fat.	Cost.
						Cents.
Shorts	7	6.17	.854	3 50	.266	6.3
Gluten feed	3	2.70	.699	1.521	.081	3.3
Clover hay	5	4.23	.340	1.790	.085	2.5
Millet hay	8	7.04	.256	3.880	080	4.0
Total nutrients		20.14	2.149	10 691	.512	16.1

Oat straw *ad libitum*.

This is another very good ration and it supplies enough nutriment for a cow producing 350 lbs. of butter fat a year. Each cow in the herd during the rest of the year received 2 lbs. of shorts a day, besides plenty of blue grass pasture.

Hartwell No. 2 yielded the most butter fat. She gave 6,197.5 lbs. of milk, 3.99 per cent fat, 247.47 lbs. of butter fat or 288.71 lbs. of butter.

Brindle No. 1 yielded the least butter fat. She gave 3,731.9 lbs. of milk, 2.88 per cent fat, 107.50 lbs. of butter fat or 125.41 lbs. of butter.

The average production for each cow in the herd was 5,360 lbs. of milk, 3.52 per cent fat, 188 lbs. of butter fat or 220 lbs. of butter.

Spotty No. 1 charged to produce 100 lbs. of milk, 40.7c and 12.6c for one lb. of butter fat.

Red Bird charged to produce 100 lbs. of milk, 70.9c and 23.1c for one lb. of butter fat.

The average cost of this herd to produce 100 lbs. of milk was 57.0c and 16.1c to make one lb. of butter fat.

Spotty No. 1 gave a profit of $25.32 and Red Bird charged $1.28 for her board.

The average profit of each cow was $12.12.

Elgin, Ill. A. J. GLOVER.

Live Stock at the Louisiana Purchase Exposition.

Provision Made for a Premium List.—Classification and Prizes on a Scale Never Before Attempted.—A Quarter of a Million Dollars Allotted for the Competition.

The Louisiana Purchase Exposition, in recognition of the magnitude and importance of the Live Stock Industry, and appreciating that St. Louis, the seat of the World's Fair, 1904, is practically the geographical center of the largest improved stock-producing area on the globe, has appropriated a quarter-million dollars to prizes for which the world's stockmen are invited to compete.

This vast sum makes possible a classification much in advance of any heretofore attempted, with prizes on a scale of generosity before unknown in the history of expositions. The largest sum previously offered by a like enterprise was $142,500, at the Columbian, in Chicago in 1893.

In the classification, every branch of improved animal industry is to have its proportionate recognition, whether it be the Percherons, Short-Horns, Pigeons or Pointers; whether the meek-eyed cows from the Channel Islands, or descendants of the American bison that once made populous the plains beyond the Missouri; whether the petite ponies from the Shetland Isles or the robust mule that has in recent years so rapidly advanced in public esteem by his proven usefulness in war, no less than in the prosaic paths of peace.

For the accommodation of the array of exhibits which will compete for the prizes offered, the management have allotted thirty acres of the most desirable ground in all the Exposition tract of over twelve hundred acres, most of which it overlooks, and upon this hill will erect the requisite buildings, combining the desired modern features of utility and adaptation with harmonious and pleasing architectual effect.

The building scheme will comprehend between forty-five and fifty structures, including thirty-three barns to accommodate eighty or ninety horses and and cattle each; several others with slightly less capacity, four octagonal barns, 100 x 100 ft., to accommodate cows to be used in a dairy demonstration, with silos and feed barns, a grand amphitheater and arena, 250 x 450 feet, for an exhibit ring, and a building for puplic sales of live stock and for stockmen's conventions, in which will also be made the exhibits and demonstrations with relation to live stock under the auspices of the Association of American Agricultural Colleges and Experiment Stations.

Aside from those usually shown various classes of horses not previously taken up at Expositions, such as those for artillery, calvalry and ambulance use in the military service, fire department, express and ambulance horses for city purposes, will be given the consideration their importance justifies.

Cattle, sheep and swine, as with horses, will be given such a wide range of prizes as to reward generously, independent of the specials given by states and breeders' organizations, the exhibitor, the breeder and the feeder, aggregating offerings so inviting that they must attract the choicest products that pasture and feedlot, supplemented by human skill, have yet evolved.

One of the most interesting and instructive features planned for the Exposition will be a comparative test of breeds of cows with reference especially to their dairy qualities in both butter and cheese production, and incidentally their gains in flesh.

Poultry, pet stock, dogs and the minor animals and fowls are to be recognized more fully than has ever before been done, and every energy will be bent to have at St. Louis in 1904, along with the other magnificient arrays of the world's most interesting and best, the most extensive and instructive presentation of animal exhibits ever assembled. * * *

Cash Value of Sharp Criticism.

P. H. Kieffer, of Strawberry Point, Ia., is a creamery butter maker, who is searching for all the intelligent criticism he can get on his work. He realizes that there is a cash value in such criticism. He was one of the butter makers who entered the six months' Educational Test, and he won handsome distinction in it. At Milwaukee he told what he had learned in that test, of which the following is a summary:

"I sent my first tub of butter to the test

234 ACRE FARM FOR SALE

One-half mile from Janesville, Wis New 12 room house, good barns, etc. Fine black soil. A great bargain and if taken at once the purchaser gets the rent. It is one of the best farms in the famous Rock River Valley and will be sold on easy terms to a good man.
WILSON LANE, Janesville, Wis.

CASH FOR FARMS We will turn your farm, business or city property into ready money at once irrespective of location; money sent to your home bank; you can step in, close the deal and get the cash; send cash price and stamp for necessary papers. Chicago Business Exchange, Real Estate Dept., 167 Dearborn St., Chicago.

FOR RENT 200 ACRE GRAIN and DAIRY FARM 16 miles from Minneapolis and 2½ miles from railroad station. One mile from church and school. Five miles from creamery, on milk route where your milk and cream is taken up daily. On free daily mail route. Five miles from beet factory where beet pulp can be had at 50c per ton. Soil a deep, heavy black loam, clay subsoil; 40 acres in fine clover; 100 acres in crops; 60 acres in wood pasture. Borders on one lake; small lake on place; small stream connecting lakes. New windmill. Eight room house. Splendid barn for 40 head of cattle and 8 horses, and 60 tons of hay. Corn cribs, grain bins, ice house, etc. Will rent for a term of years to party who has cattle to put on the place. Address
C. L. SMITH,
Court House. MINNEAPOLIS, MINN.

GINSENG CULTURE BETTER THAN A GOLD MINE
You have the land, I have the seed and plants. Get rich quick. Others do—you can do the same. $5,000 to $20,000 made in from three to five years cultivating Ginseng. Will pay from $16,000 to $30,000 per acre. A medical root, will grow on farm or in your gardens, no experience necessary. Write for particulars.
G. BETTS, Ginseng Gardens, EVANSTON, ILL.

ILLUSTRATION.

BLIZZARD CUTTER AND SHRDDDER.

We are picturing here a piece of machinery that makes direct appeal to every corn raiser who wishes to get the greatest value out of the fodder. It is the Blizzard Cutter and Shredder, the prize product of the Joseph Dick Agricultural Works, Canton, Ohio. Elsewhere is an advertisement which sets forth in brief the special merits of the machine. It has grown directly out of the need for a single piece of machinery to do everything in the way of fodder preparation. It goes farther and serves equally well for hay and straw cutting. Through its pneumatic tube it elevates to any height, giving it special value for the filling of silos. To many of our readers it is a familiar sight, they being aware from long experience of its great worth in this particular field. To such as are not we suggest writing the manufacturer for the catalogue and learning more about it before silo filling and winter feeding time comes on.

ILLUSTRATION.

VEHICLE ECONOMY.

The word economy has so many different meanings that it is often misinterpreted. In the matter of buying vehicles; to one it may mean doing without altogether; to another, using the old rattle trap affair that long ago outlived its usefulness; another will tell you that it means to buy the cheapest priced style to be found; while another, after careful consideration, will decide that it is true economy to buy from an old established manufacturer who has a deserved reputation for making first-class goods and selling them at moderate prices.

One concern which meets these requirements is our advertiser, the Elkhart Carriage & Harness Mfg. Co., of Elkhart, Ind. We show one of their late patterns above. These people have been manufacturing high grade vehicles and harness continuously for thirty years and during all of that time have sold only direct to the consumer. This fact, taken with the high character of their work, constitutes the truest economy for the vehicle buyer, who thus gets his goods at first hands without paying unnecessary profits. The Elkhart Co. actually manufacture everything they sell and can show the goods. Hundreds of buyers come every year to Elkhart, some from long distances, to select in person, as they more than save their railroad fare on the price. The new catalogue is now out and shows 195 styles of vehicles and 65 styles of harness. It is a book of 224 large pages, showing photographic views of all their styles. From this catalogue one may order as safely as from a store exhibit, for this Company takes all the risk of satisfying the purchaser. A copy will be sent free to any reader. Write to-day and mention HOARD'S DAIRYMAN.

in Chicago in May," said Mr. Kieffer. "I placed it at 96 points, and kept a tub of the same butter in the cooling room, to make my own observations on the day the butter was to be examined by the experts in Chicago. On that day, eight days after I forwarded my tub, I found the tub I had kept had turned acid a trifle, and I began to hope that the tub I had forwarded had got lost, and that I wouldn't hear from it. I got the criticism, however, which was as bad as I had anticipated. Expert D. B. White wrote me that the flavor was unclean, probably because the milk had been poor. There was too much moisture in the butter, and it was a trifle rancid. From this I learned that I would have to look out for butter that scored 96 points, unless the milk was of the best quality.

The June butter, said Mr. Kieffer, was a little milder in flavor, and the butter of each month was better than the preceding months, mainly because of the advice and criticism from the tester, until he scored a perfect butter at the September test. Concluding, he made a hearty appeal for the association to give unanimous support to another test to be begun immediately, and recommended that the secretary be paid a good salary for looking after the work. The test was conducted by the association and assisted by the Department of Agriculture.

The expert said that the poor butter was caused by bad milk. Of course, the patrons were responsible for the quality of the milk. Now the question arises, would they court and accept criticism and advice as to the quality of their milk with the same spirit that Mr. Kieffer accepts it as to his part of the work?

If they could bring their milk to the same tribunal of fearless criticism that the butter maker has to bring the butter, they would soon learn their mistakes as he learns his. It is a pity that the milk production part of butter making, which is just as important as any other, can hide behind the creamery and never hear the verdict the market renders. Yet the patron is responsible as much as the butter maker for the quality of the butter.

DAIRY MARKETS.

ELGIN, Ill., June 8—Butter—Ruled firm on the Board of Trade today, selling at 22c a pound, an advance of ¼c from last week. The output for the district for the week was 828,000 pounds.

CHICAGO, Ill., June 8—Butter—Firm; creameries, 15@22c; dairies, 15@18¼c.

Eggs—Steady; at mark, cases included, 13¾@14¼c.

Cheese—New steady; Twins, 10½c; Daisies, 11c; Young Americas, 11¼@11½c.

Cattle—Prime beeves, 1,250 to 1,500 pounds, 5.30@5.50; choice to extra steers, 4.90@5.25; fair to good export and shipping steers, 4.70@4.95; medium beef steers, 4.40@4.65; plain beef steers, 4.00@4.35; common to rough, 1,000 to 1,200 lbs. 3.50@3.80; good to choice feeders, 3.85@4.70; good to choice heifers, 4.15@4.85; poor to plain stockers and feeders, 2.85@4.00; fair to good cows and heifers, 3.20@4.10; good cutting to fair beef cows, 2.40@3.10; common to good canning cows 1.40@2.35; bulls, poor to choice, 3.20@4.35; veal calves, good to fancy, 5.75@6.75; calves, common to fair, 3.50@5.50; corn-fed western steers, 3.85@5.40; Texas bulls and grass steers, 2.75@3.30; Texas steers, fair to common, 3.85@4.75.

Hogs-Good to prime heavy shipping 5.95@6.07½; good to choice heavy packing 5.80@5 95; plain to choice heavy mixed 5.75@3.90; selected butcher weights 5.85@6.00; assorted light, 150 to 195 lbs. 5.65@5.90; common to good light mixed, 5.65@5.80; thin to choice, 50 to 130 lbs., lots 5.20@5.70; stags and rough lots, 3.60@5.50.

Sheep—Choice to prime native wethers, 5.00@5.30; plain to good mixed lots, 4.00@5.00; fair to prime western yearlings, 5.00@5.75; fair to fancy native and western ewes, 3.85@4 50; plain ewes and breeding stock, 3.25@3.70; culls and tail end stock, 2.00@3.00; native lambs, poor to fair, 3.50@5.50; good to prime native lambs, 5 60@7.00; fair to prime native lambs, 5.60@7.00; fair to prime western lambs, 5.50@7.15; spring lambs, 4.00@7.25.

MILWAUKEE, Wis., June 6—Butter—Creamery—extras, 21½c; firsts, 18@19c; seconds, 16c; process (renovated) 16@17c; whey, 10c. Dairy, fancy, 17c; lines, fresh, 14@15c; packing, 13c; grease, 6@9c.

Cheese—American, new, full cream—Twins, 10½@11c; Young Americas, 11@11½c: Daisies, 11@11½c; Longhorns, 11½@12c; low grades, 9@10c. Brick, fancy, new, 10½@11c; low grades, 9@10c. Limburger—Fancy, new, 10½@11c; low grades, 8@9c; Swiss, drum, old, choice, 15½@16c; drum, No. 2, 13@14c; Block, choice, 14@14½c; block, No. 2, 12@13c.

Eggs—Strictly fresh laid, cases returned, 14c; dirties, 12c; seconds, 10c.

MUSCODA, Wis., June 6—Cheese—Offerings were 311 boxes Twins and 8 boxes prints. Sales: 161 Twins at 10¾c and 150 Twins and 80 prints withdrawn.

APPLETON, Wis., May 28—Cheese—Nineteen factories offered 1 000 boxes of Twins and all except 284 boxes sold as follows: 620 at 10⅜c, and 96 at 10¼c.

HORTONVILLE, Wis., May 28—Cheese—The offerings were 750 Twins and 99 double Daisies. Sales 145 Twins at 10½c, 478 at 10⅜c, and 99 double Daisies at 10¾c. Market active.

PLYMOUTH June 2 -Cheese-Twenty-seven factories offered 3,731 boxes cheese. Forty Ameri-cas were passed on, the balance selling as follows: 428 cases Longhorns, 11c; 2,150 Daisies, 11c; 370 Twins, 10¼c; 193 at 10⅜c; 490 Young Americas, 10¾c, 60 at 10⅝c. Market active and firm.

FOND DU LAC, Wis., June 8—Cheese—Sales at Call Board today: 138 Twins at 10⅛c, 40 at 10¼c and 105 Daisies at 11c, 375 at 11⅛c. Market active.

BRILLION, Wis., June 4 —Cheese—The sales of cheese on Brillion Call Board: 851 Daisies at 11c: 359 Twins 10¼c; 28 at 10⅜c; 36 Young Americas at 11⅝c, 15 at 10¼c; 19 Cheddars at 10c. Market strong and active.

SHEBOYGAN, Wis., June 3—Cheese—On the Call Board here today the offerings and sales comprised 2,384 boxes of cheese as follows: 67 boxes Twins at 10¼c; 1,013 Daisies at 11c; 472 Young Americas at 10⅝c; 165 at 10¾c; 630 cases Longhorns at 11⅛c; 37 at 11¼c Bidding was the most lively of the season.

SHEBOYGAN FALLS, Wis., June 3—Cheese—Twenty three factories offered 2,833 boxes of cheese on the Call Board today and all sold as follows: 26 Twins at 10⅜c, 67 at 10¼c ; 793 cases Young Americas at 10⅝c; 1,021 Daisies at 11c, 918 cases Longhorns, 11c, and 8 at 10⅞c. Market active and firm.

BOSTON, Mass., June 8—Butter—Creamery, western, extra, 23c; western firsts, 22@22½c; dairy, 16@22c; imitation creamery, 17@19c; ladle, 15@17c; box and print, 17@23½c.

Cheese—Choice, 10¾@11¼c; Wisconsin Twins, 10¾@11¼c.

Eggs—Nearby, 21c: western selected, 16¼@16½c; fair to good, 15@16c; Illinois, 16½c; western dirties, 13½@14c.

PHILADELPHIA, Pa., June 8—Butter—Market firm. Solids 23c. Nearby prints 24; western, 23c.

NEW ORLFANS, La., June 8—Butter—Market firm; extras, 22½@23c; ladles 16c.

LIVERPOOL, June 8 —Butter—Good United Sates steady, 75s.

Cheese—American finest, white dull, 54s 6d; colored, quiet, 57s.

Latest quotations for fancy creamery: Baltimore, 23c; St. Louis. 22@22½c; Cincinnati, 23½c; Newark, N. J., 22c; Buffalo, 22½c; St. Paul, 20½c; Minneapolis, 20½c.

UTICA, N. Y., June 8—Market quiet at unchanged prices. Large Cheddars, 2,000 at 10⅜c; small, 3,000 at 10½c.

CANTON, N. Y., June 8.—Cheese — Offered 55 oxes of large cheese; 2,524 Twins and 1,074 tubs b butter. Large cheese sold at 10 3-16c; Twins 10⅜c; ofButter—22½c.

BALTIMORE MARKET.

BALTIMORE, June 3—Butter—Notwithstanding there has been a further increase in the receipts of creamery the market has maintained a firm tone since our last issue. The demand both for consumption and storage purposes continues very good. There is no disposition on the part of receivers to force sales, hence it is a case of buy or not, just as you choose. The quality of the stock arriving (with but a few exceptions) has been very satisfactory. Several long lines of extras have gone in the freezers. Firsts—The supply is insufficient to satisfy the demand. Second—Unless well up in quality are slighted. Imitation creamery is very scarce. Fancy stock is in active demand. Ladles, so far this week, have been in more liberal supply; the stock as a rule is not very attractive. Packing stock is in moderate receipt and quick demand when the quality is desirable. Blocks and prints—When fresh and free of garlic meet prompt sale. The market closes fairly active and very firm on all attractive offerings. N. B.—Use nothing but well seasoned clean tubs and be sure to see that they are thoroughly soaked as there is still considerable complaint of mildew and mould. Try and obviate this very great nuisance.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Wanted—An experienced man to take charge of milk route. Must be a single man and a hustler. State wages and references. Wanted immediately. S. G TAYLOR, Mauston, Wis. 18-3

Two choice young Guernsey bulls for sale. MRS. A. W. LEHMANN, Neosha, Dodge Co., Wis. 12-8p

Position Wanted—One of responsibility for the combined work and management of manufacturing butter, cheese and process butter. Years of experience. All goods warranted. Address H, care Hoard's Dairyman. 17-3

Wanted—To rent for a term of years, good dairy farm. Large buildings close to town in Southern Minnesota or South Dakota. C. W. WALLINE, Cambridge, Ill. 17-2

Wanted—Two good milkers at once, Germans preferred. $25.00 per month and board. A. B. NOKES, Springfield, Ill. 17-2

Practical Man Wanted—To take charge of an Indiana dairy and push sales. Single man preferred. Must be an up-to-date hustler. Address "INDIANA," care Hoard's Dairyman. 17-3

Are You Color Blind?—If not, you will appreciate the natural golden colored product of the Guernseys. Pure bred bulls and grade heifers for sale. A. H. HINMAN, Allenville, Wis. 17-4

For Sale—Fine herd of dairy cows, three miles from Oklahoma City, O. T. Box 336. 17 2

Position Wanted—Experienced butter maker wishes to change position. Have taken Dairy Course at Ames, Iowa. Good references. Address T, care Hoard's Dairyman. 15-5

A Registered Guernsey Bull 15 months old for sale. A very fine animal. Inquire of J. S. HUNTER, Pickett, Wis. 12-tf

For Sale—Four young registered Guernsey cows, all fresh. J. E. STORY, Stanley, Wis. 11 tf

Wanted—Second-hand De Laval or Sharples Safety Hand (hand size) separators. Never mind if out of order, but must be cheap. CREAM SEPARATOR SUPPLY CO., Council Bluffs, Ia. 16-3

Half Price—Three registered Jersey heifers one year old and under. First check for $100 takes them. Satisfaction guaranteed. WALTER ZIMMARMAN, Moray, Kans. 18-2

For Sale—Davis Cream Separator, 450 lbs capacity, used 2 months, good condition. J. KOHL, Reeseville, Wis. 18-2

For Sale—One No. 3 De Lavel separator in good order, used a short time only. Putting in larger machine. FOREST HOME FARM, Purcellville, Va. 18-2

Do You Want—A Hay Fork Returner? Every farmer having a barn should have one. A hummer for agents. Circulars free. ROONEY RETURNER CO., Box D., Independence Iowa. 50-tf

Wanted—Single man on large dairy. Only good milkers need apply. F. W. ADAMSON, Lake Bluff, Ill. 4-tf.

Buff Jersey's latest book on Farm Stock and Dairy Work is full of practical things for practical people. The Silo, how to build and fill; ensilage, its value; soil, crops, variety and how to grow. Swine, poultry and many other subjects ably treated. Send 25c for copy. Monmouth, Ill. 47-tf

Fine Dairy Farm for Sale—Near St. Paul, Minn. 210 acres good land with ample buildings of all kinds. Page fence cedar posts. Pure bred Holstein cattle and Yorkshire swine sell readily at good prices. Good markets for all dairy products. Will sell with or without stock and other personal property. Easy terms. Enforced removal to California only reason for selling. T. S. TOMPKINS, Pasadena, Cal. 15-tf

Very Low Rates to California and Return—Via the North-Western Line. First-class round-trip tickets on sale July 1 to 10, inclusive, to San Francisco and Los Angeles. Favorable limits and stop over privileges and choice of routes. The overland limited, most luxurious train in the world, leaves Chicago daily at 8 p m. Less than three days en route. Drawing room and compartment cars, observation cars, dining cars, buffett-library cars (barber and bath), electric lighted throughout. Three trains a day from Chicago to the Coast through without change. Daily and personally conducted tourist car excursions to California, Washington and Oregon. For particulars apply to ticket agents Chicago & North-Western R'y. 16-7

Special Excursion Rates to Colorado, Utah and the Black Hills—Via the North-Western Line. Beginning June 1st excursion tickets will be sold to Denver, Colorado Springs, Pueblo, Salt Lake City, Hot Springs, Deadwood, Lead and Custer, S. D., etc., good to return until Oct. 31. A splendid opportunity is offered for an enjoyable vacation trip. Several fine trains via the North-Western Line daily. Apply to agents Chicago & North-Western R'y. 16 sp

Very Low Excursion Rates to North American Saengerfest at St. Louis, Mo.—Via the North-Western Line. Excursion tickets will be sold at reduced rates June 16th to 17th, limited to return until June 22, inclusive. Apply to agents Chicago & North-Western R'y.

Excursion Rates to Milwaukee, Wis.—Via the North-Western Line. Excursion tickets will be sold at reduced rates June 11 and 13, inclusive, limited to return until June 15, inclusive. on account of State Meeting United Commercial Travellers. Apply to agents Chicago & North-Western R'y.

"Short Jaunts for Busy People" is the title of a handsomely illustrated booklet issued by the Chicago & North Western R'y, briefly describing nearby summer resorts, with information as to summer hotels and boarding houses, railroad and hotel rates, etc. Sent on receipt of 2 cent stamp. Address W. B. Kniskern, Passenger Traffic Manager, Chicago. For rates. tickets, etc., apply to agents Chicago & North-Western R'y. 18-sp

Creamery Building.

[Paper read by OSCAR ERF, (Illinois Experiment Station) at the Wisconsin Buttermakers' Association, Waukesha, Wis.]

The keen competition in modern butter making necessitates systematized work. The minor details closely allied, in this vocation, must be taken into consideration in order to lessen the cost of manufacturing butter and at the same time to produce an improved article. To do this we must look for the most improved and economical methods, take advantage of all natural means, locate judiciously, manage affairs on business principles, and look for more convenient arrangements. The latter is the easiest to obtain and yet in glancing over the different factories that are in existence at the present time, we find this point sadly neglected. There is a need for better creamery buildings—buildings that are more convenient in arrangement so that they can be kept sanitary.

In launching into this business we must first look for a suitable location. The most necessary requirement is to locate near the center of a milk producing district, or rather in a section of the country where the people are naturally inclined toward dairying. It is essential to have a sufficient number of cows that will insure enough milk to make a creamery profitable.

The total cost for running a creamery and marketing the product, including interest on the investment and provision for a sinking fund, ought not to exceed 3½ cents for every pound of butter made. Under favorable conditions this cost ought to be reduced to 3, or even as low as 1½ cents. The smallest practical creamery cannot be operated for less than $4 or $5 per day. It becomes evident then that the daily product should be over 150 pounds as a safe minimum. Consequently no creamery should be put into operation unless having control, or a promise, of about 300 cows.

A reliable supply of good, pure water is another requisite of great importance. Cold water is advantageous in every respect and at the same time saves ice.

The surroundings should be such as to insure pure air, with little dust and a minimum amount of direct exposure to sun light. A lawn around the creamery with some trees and shrubs will aid in purifying the air besides making the surroundings more attractive.

A creamery should be located within reasonable distance of some shipping point where the product can be marketed to the best advantage, and so that the factor of transportation shall not enter in to offset the profit.

DIMENSIONS.

It is rather difficult to give the dimensions of a creamery to suit all conditions. However, there is this fact to be borne in mind, that the working rooms of a creamery should be built small and compact, and convenient in order to save labor in keeping the creamery clean. As an approximate estimate I should say that a creamery handling milk from 400 to 600 cows should contain 900 to 1,200 square feet of floor space, not including coal space and store room.

PLANNING.

Since dairying is carried on in such a wide range of latitude and longitude and to such a varied extent, it becomes impossible to have a set plan for a creamery suitable for all conditions and requirements. Hence, the wisest plan I can suggest, if a new creamery is to be erected, is to put it in the hands of a competent and practical creameryman of wide experience, and have him outline a building to suit the particular situation. The extra remuneration for the service of such a man is soon regained in the saving of labor and expense.

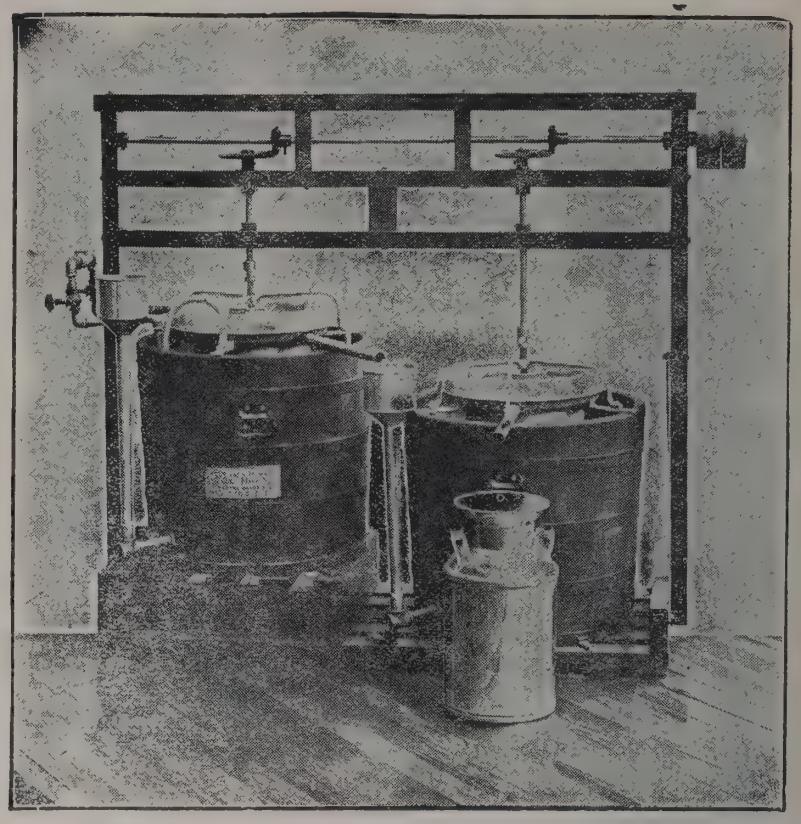
There are, however, a few essentials which every butter maker should think of in arranging a creamery. He should try to arrange his building and machinery to secure both convenience and cleanliness and so as to perform the labor in the factory in the easiest possible manner and under the most economical conditions. All who have had experience in a creamery know of the loss of time and the waste of labor resulting from some seemingly small mistakes in the construction of the building, as for instance putting a door in the wrong place, or locating the boiler room at a distance, or putting the receiving platform three or four feet higher than the bed of the highest wagon that comes to the creamery, or locating the separator and cream vat at a great distance apart which necessitates the cleaning of long milk or cream conductors. These faults should be foreseen in order to save the operator as much work as possible and to enable him to reach given points easily and without unnecessary steps in a round-about way.

CONSTRUCTION.

In constructing a creamery we must continually bear in mind that whatever we build must be built so that it can be kept in a sanitary condition. The first essential is to find some way to dispose of the creamery sewage in a cheap and effective manner. This can easily be done, in any location where the solid rock does not come to the surface, by means of a septic tank and filter bed to purify the creamery sewage. This septic tank is nothing more than a solidly built vault or box of such capacity as to hold the sewage that runs from the creamery every twenty-four hours. The object of the septic tank is to settle the organic matter in the sewage and at the same time serves the purpose as a receptacle for incubating the bacteria which decompose the organic matter into a gas or a solution, which is carried through into a filter bed where these constitutents are absorbed by the soil, and the water that is liberated therefrom is purified.

The septic tank may be constructed of either brick, grout, or wood,—brick or grout being preferable. It should be so arranged that the rush of the incoming sewage will be checked before it reaches the tank in order not to disturb the flocculent matter that is settling in the tank. It should also be arranged with cross partitions between the inlet and outlet so that the floating and settled material will not move with the current of water and obstruct the outlet of the tank. The tank must be located in the ground under the frost line so that it may be kept at a uniformly warm temperature in order to induce the growth of the bacteria which will decompose the organic matter in the sewage. Large quantities of either hot water or a strong disinfectant must not be put into the tank as such things will destroy the germ life. With these precautions the organic matter will thoroughly decompose and the tank will remain practically free from sediment providing that little inorganic material, such as sand and mud, has been deposited in the tank, and consequently it is not necessary to clean the tank more than once a year.

If flowing water is at hand a septic tank is all that is necessary since decomposition has gone on to such an extent that no odor arises. Under all other conditions a filter should be used in connection with the septic tank. The filter bed into which the sewage flows can be constructed in various ways, depending on the soil of that particular locality in which the plant is situated. The most common, and probably the cheapest, way to make this filter where the soil is composed of sand, loam, or clay, is by running a tile drain into a field, and from this a series of branches so as to distribute the sewage over a considerable area.



Drain tile should be laid on the same level, intercepting these sewage tile, for the purpose of taking up the superfluous water and thus prevent the ground from becoming saturated. If the soil is of a hard texture, or if a hard pan lies near the surface, the sewage can then be discharged into a small bed of sand which is thoroughly drained and aerated, and which acts as an excellent sewage purifier. This method of sewage disposal is very economical. The cost of such a plant varies from $20 to $80 depending upon the construction, the size of the creamery, and the particular locality in which it is situated.

BRICK VS. WOODEN CREAMERY.

There is no question but what a brick building is not only the most sanitary but is also the cheapest in the long run. Although the first cost may be somewhat greater, in some localities of the central states, for a brick than for a frame building, yet when the high insurance and the necessary repairs of a frame building are considered, it will be found that the brick or grout creameries are not too expensive as is commonly thought, or too elaborate for creamery work.

In choosing either brick or frame walls, the building should be placed on solid foundation walls. This foundation base should not be less than 18 inches in depth and 15 inches in width. It can be constructed of either grout or brick, grout being the cheaper of the two. On this foundation, a wall should be built 15 to 18 inches high, the width depending on

A GREAT SUCCESS.

WRITE FOR OUR CATALOGUE

the material used. If common wall stone is used, about 15 to 18 inches would be the proper width; if range stone, 10 to 12 inches would be sufficient; if made of solid or hollow brick, 12 inches would be ample in width. If the building is of brick, a two course wall would be sufficient for a single story building. The walls should have an air space and should be bound together by means of wire stays. If the walls are to be constructed of wood, either 6 x 6 hemlock sills can be laid on the foundation on which should be placed 2 x 4 scantling, or a box sill may be made of Norway pine, from 2 x 8 planks.

The scantling should be boarded on the outside with cheap lumber, papered and sided on the paper with siding. The inside of the 2 x 4's should be lined with paper, nailing an inch strip on the scantling, reline this with paper and follow it with common ceiling. This will make a very cheap and effective wall with two air spaces. Lath and plaster may be substituted for the first layer of paper on the inside of the scantling, but only at greater expense and with no particular advantage.

An artistic, durable and fire proof roof can be made by the use of slate; however, where cheapness is desired a galvanized roof without cornice, is much cheaper an equally as good. The rafters on such a building may be of common hemlock or yellow pine, and of 2 x 5 in size for shingle, or a galvanized roof, depending somewhat on the width of the building. If slate is to be used the rafters should be 2 x 6.

FLOORS.

It is very essential in every creamery to have a good sanitary and substantial floor. There is no question but what cement fills all the requirements, and if constructed properly, is much superior to wood, I think all buttermakers will agree on this point.

The chief objection to cement floors is that they are too cold and moist for the health of the operator, and this is the reason more creameries do not have them. This difficulty is entirely a fault in the construction of the floor and can be easily overcome by laying the cement floor in the following manner: Lay the cement floor at least one foot above the outside ground surface. First lay a tile drain, close to the foundation, around the inside of the building, and to make things better lay one or two drains through the center of the building and connect this with an outside drain. Fill in with cobble stones or broken stone to the depth of three or four inches, then fill in with three or four inches of cinders. If the cinders are more easily obtained, it is preferable to use them throughout. The next three or four inches of cinders should be mixed with common cement or sand, applied evenly and thoroughly tamped, using an approximate proportion of ⅓ common cement, ⅓ cinders, and 1 ⅓ sand. On the top of this spread a coat 2 inches thick of Portland cement, ⅓ cement and ⅔ coarse gravel. Finish with a ½-inch layer of Portland cement mixed proportionately half sand and half cement. Let this thoroughly harden and a good floor can be insured if the sand used is clean and well mixed, with cement, the cement fine and freshly burned, and the mixture not moistened too much so that it can be well tamped.

This makes a floor that is more expensive than is commonly advocated. However, it is economy in the long run to pursue this or a like method, as a cheap cement floor in a creamery is next to no floor. If the proper thickness of cinders has been used below it can be guaranteed that the cement floor will be dry. The objection of floors being cold can be readily overcome by laying 2½ or 3-inch tile in the first layer of the cement, through these tiles run 1-inch or ¾-inch steam pipes. Connect this steam pipe on one side with the exhaust pipe of the engine, on the other side with the sewer. Regulate the amount of exhaust steam by means of a valve to go through these pipes which act as condensers and at the same time will warm the floor of the creamery, making it more healthful than any wood floor that can be constructed. Hence, I can conceive of no case where the wood floor should be used unless the creamery is a two-story building, or with a cellar underneath, and even in this case it would seem to be economy to use a cement floor on top of the wood floor. In this case the wood floor must first be covered with paper, two or three inches of cinders must be spread on the floor to allow for the contraction and expansion of the wood, and cement on this as before.

In creameries it is always advisable to have the floor corners rounded and a wainscoting of 18 inches to 2 feet, built of cement. This is advantageous in a brick or even a frame building.

A cement floor in a creamery should have a slant, of ¼-inch to every foot, toward a drain. This drain is sometimes made of cast iron, but it can be made of cement which is just as durable and much cheaper. The bottom of this drain should have a slant of ¼-inch to every foot toward an inlet to an underground drain which should be connected at this point with a bell trap to prevent the odors from the sewer coming up into the factory.

Where it is necessary to build a wooden floor in a creamery, it is wise to have the joist not more than eight inches apart in order that the floor can be firmly nailed and to prevent warping. At the same time the joist should always be laid full length on the sills and cross sills. To be economical in material, never span more than twelve feet without having a support. The flooring should be of the best white oak, or if this is not obtainable, use good Georgia pine. The flooring should be well matched and dressed, 1½ to 2 inches in thickness and should be covered with two coats of boiled linseed oil, applied hot and thoroughly ironed in with hot irons.

THE ELEVATION OF CREAMERY FLOORS.

In building a creamery it is very essential to know what method is preferred for conveying the milk from the receiving vat to the cream separator, whether this is to be done by gravity or with pumps. Different floor elevations are required in these methods and each has its advantage and disadvantage. It is merely a question with the operator whether he prefers to climb four or more steps, or to clean one of our simple modern milk pumps.

The machines in a creamery should be so placed as to avoid the use of long conductor pipes and the pipes should have as few angles and joints as possible. Special care should be taken to select pipes that are smooth on the inside. Tinned copper or brass pipes are the best, although drawn steel, tinned on the inside may be used to advantage. Rubber hose should never be used for conducting milk, or cream, even for the shortest distance.

Another necessary adjunct to a modern creamery is a good, well insulated refrigerator. As the conditions vary so much in a creamery it is rather difficult to estimate the size of the refrigerator, but a practical height should never be less than 6½ feet and the ice box above it should be as high as can be made under the rafters, although this never ought to be less than five feet. In building a refrigerator an important point is to have it well insulated so as to retain the cold temperature.

The method of insulating these refrigerators differs greatly, but in running a series of tests at our Station last year we reached the conclusion that some insulating material in the center of the wall, well protected from moisture by double thickness of paper and boards on each side and with a dead air space on each side of this insulation, gives not only the best results, but is also the cheapest. This insulating material can consist of rock cotton, granulated cork, or planer shavings. Since the shavings afford an excellent place for vermin it is very necessary that they be disinfected with some poisonous solution like copper sulphate or corrosive sublimate, then the shavings must be thoroughly dried.

Great care should be taken in building a good, well insulated floor in this refrigerator. Not only should the floor be insulated at the sides, but beneath the floor the space between the ground and the boards should be filled in with 4 to 6 inches of cinders.

It is always well to have the ice box located in such a position as to induce the greatest movement of air in the refrigerator; this is very essential to good refrigeration. Hence the ice box placed above the refrigerator seems to be the most efficient location. The refrigerating room below should be connected with the ice box above by means of a flue on one side to receive the upward current of warm air and another flue on the opposite side to receive the downward current of cold air.

In building such a refrigerator it is almost necessary to build an ante room to it, for while entering the refrigerator one door can be closed while the other door is open. The inside of the refrigerator should be painted with some cold water paint.

Where ice cannot be secured from ice companies it is necessary to have an ice house in connection with a creamery. The dimensions of the ice house depend upon the purpose and the capacity of the creamery. Ordinarily an ice house of 150 tons capacity is ample for a creamery handling from 8,000 to 10,000 pounds of milk a day. As a cubic foot of ice weighs 55 pounds an approximate estimate can be made from the above for the size required for the conditions in this latitude.

An ice house may be built of single or double walls, depending upon the ease and cheapness with which ice can be secured in winter. It is not generally advisable to have an ice house directly connected with the creamery building, but it should be located close by in order to save labor in getting ice.

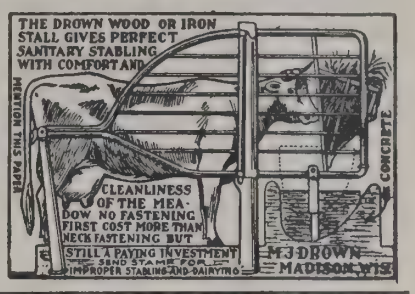
The inside walls of a brick creamery may be plastered and painted or the rough walls may simply be painted, with two coats of oil and white lead and a third of white lead and varnish; both methods being sanitary, the latter being the cheapest.

The windows should be large and placed well above the floor and should be arranged so as to drop from above as well as below, in order to secure good ventilation. The creamery should be provided with a ventilator on the roof and passages connected with the rooms below to carry off the steam and heat.

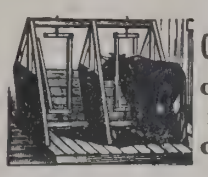
The boiler of a creamery is really a part of the building. It is a difficult matter to estimate the size of a boiler for a creamery, but I will say that it should be large and of good capacity. A large boiler may not be as economical as a

Goodwin's

T. D. Goodwin & Co.,



USE GOODWIN'S FLY KILLER this season and make your stock comfortable. Your cows will give 25 per cent more milk; your beef cattle will fatten with one-half the feed and your horses will do their work with ease. Goodwin's Fly Killer will protect stock from flies when in pasture as well as in stable. It's convenient, cheap, practical. It's a sure lice killer and will keep stables and hog pens in a sanitary condition. Prices: Gallon 75c; 5 gallons $3.00; 10 gallons $5.50. Good sprayer for applying same 50c, or send $1.00 for Sprayer and enough Fly Killer to protect 150 cows. Agents wanted. T. D. GOODWIN & CO., Columbia Station, Ohio.



SHOO-FLY THE ANIMALS' FRIEND

Half cent's worth saves 3 quarts milk and much flesh. Kills every fly it strikes; keeps off the rest. Harmless to man or beast NO LICE in poultry house or any place it is sprayed. If your dealer does not keep it, send $1.00 for Improved Three Tube Sprayer and enough Shoo-Fly to protect 200 cows. Cash returned if cows are not protected.

Chain or Pin Fastened.

Are self adjusting and noiseless. Fasten themselves open when animal is out; swing freely when latch is closed; opened and closed without removing mittens or gloves; keep cattle clean with most freedom of motion; blind bolted and cannot get loose in joints; made of best selected hardwood and furnished with chains or pins as desired.

Safest, Strongest, Most Convenient fastening made. Cheapest to put in and save room in barn. Send for Stanchion Catalog to J. K. WILDER & SONS, BOX 11, MONROE, MICHIGAN.

"I wrote to Dr. Pierce for advice though I thought surely I would die."

"After my baby came in January, 1900," writes Mrs. Nancy Abner, of St. Paul, Ark., "I suffered severely from all sorts of aches and pains, until the following May, when I read one of your pamphlets, treating on female diseases. I wrote to Dr. Pierce for advice, although I thought surely I would die, as our physician told me I was more liable to die than to get well; your fatherly advice caused my health to be restored. I took five bottles of Dr. Pierce's Favorite Prescription, three of 'Golden Medical Discovery' and three vials of 'Pellets,' together with your other remedies, and I am now able to do all my work."

Weak and sick women are invited to consult Dr. Pierce, by letter, *free*, and so obtain without charge or fee the advice of a specialist upon diseases peculiar to women. All correspondence is held as strictly private and sacredly confidential. Address Dr. R. V. Pierce, Buffalo, N. Y.

The invitation to consult Dr. Pierce, by letter, *free*, is not to be confused with offers of "free medical advice" made by irresponsible persons who are not physicians and are professionally and legally disqualified for the practice of medicine.

Dr. Pierce's Favorite Prescription is a safe and reliable remedy for the cure of womanly ills. It establishes regularity, dries weakening drains, heals inflammation and ulceration and cures female weakness.

FREE. Dr. Pierce's Common Sense Medical Adviser is sent *free* on receipt of stamps to pay expense of mailing *only*. Send 21 one-cent stamps for the book in paper covers, or 31 stamps for the cloth-bound volume. Address Dr. R. V. Pierce, Buffalo, N. Y.

A Steel Stanchion beats anything you ever saw for tying cattle. Lighter, stronger, neater. Swings on chains. Not in the way when lying down. Agents wanted. Write for special terms and prices. Jas. Boyle, Mfr., Salem, O.

THE NEW PATENT Cow Stall AND FEED TROUGH.

This is the only Cow Stall with a centering hinge. Stalls all fold back to manger as the cows go out the barn. When ready for use, by starting one stall all come into position. No post at the gutter. Send for circulars. R. A McLERY & CO., Palmyra, Wis.

Keeps Cows Clean.

Swings forward while getting up or lying down. Looks back while standing Full particulars free.

E. PRESCOTT, Beverly St., Boston, Mass

small one, where run to its greatest capacity, however, it requires less labor to fire such a boiler, which is a greater factor than fuel in many of our creameries. There is no particular preference of boilers, but I will say that the better the boiler is insulated on the outside, as the brick boilers or the modern marine boilers, the better it is for all purposes in a creamery.

I believe in a sterilizer and dry room for a creamery and this can be most economically located near the boiler where the heat of the boiler, which would be otherwise wasted, will serve to dry the utensils.

Water should be piped with black iron pipes to all vats, to the sink, the churn, and in case of a whole milk factory, to the skim milk tank.

The skim milk tank of a whole milk creamery should be lined or made of galvanized iron in order that it may be kept clean and sanitary. The ground around the place where the skim milk is drawn should be paved in such a way that the drip will run off into the sewer. It is necessary to flush this place every day during the summer to keep conditions sanitary around the creamery.

The exhaust steam should never be wasted but utilized for heating the building or scalding the skim milk in order to keep it sweet until it is fed.

THE HEATING SYSTEM.

There are a great many different schemes for heating a creamery and yet I might say that a majority of the creameries have no system at all. The simplest heating system and the one that works best is where steam is forced through a series of heating coils arranged in the rooms of the creamery and connected with the hot water tank above. The un-utilized steam that passes through these coils is thereby not lost, but serves a purpose for heating the water in the insulated tank above.

There are a great many other minor details too numerous to mention in a paper of this kind, but in planning a creamery these little points will come to a practical man.

Summer Meeting of the Western Guernsey Breeders' Association.

ED. HOARD'S DAIRYMAN:—The summer meeting of this association was held at the Helendale farm of Mr. Fred Rietbrock, Athens, Wis., June 3rd, 1903.

The association members and invited friends were Mr. Rietbrock's guests from the time they left Milwaukee, and occupied a Pullman, and Pres. Whitcomb's private car.

Fully seventy-five from the southern part of Wisconsin and from Michigan and Minnesota were in attendance.

This association numbers among its members nearly all of the Guernsey breeders of the middle west and nearly all of these were present, and with them came Professors Carlyle, Russell, Moore and Woll of the Wisconsin College of Agriculture, Prof. Haecker of Minnesota, ex-Gov. Hoard, and Herdsman Danks of the Wisconsin Station, and Mrs. Adda F. Howie and F. H. Scribner, Jersey people. Nearly or quite 300 local farmers with their wives attended the meeting and partook of the bountiful noonday lunch.

Excellent papers and discussions were a part of the program, and the *Athens Record* was out by five o'clock in the afternoon with a full report of the meeting. Mr. Fred Vogel, Jr., Milwaukee, Wis.; Mr. C. W. Wilcox, Des Moines, Iowa; Mr. W. S. Guilford, Racine, Wis.; Mr. G. A. Freeman, Pewaukee, Wis., Mr. F. W. Seymour, Milwaukee, Wis., were elected for membership in the association, this making the total membership 69 from six states.

The forenoon was spent in driving over the beautiful country about Athens, as the guests of the people of the town and surrounding country. The soil and crops were a revelation to many who had never been in north central Wisconsin, and many were heard to say that they believed that from an agricultural standpoint Marathon was the best county in the state.

The business meeting adjourned at four o'clock, when two hours were very enjoyably spent in looking at Mr. Rietbrock's fine herd of Guernseys. If anyone came with the idea that all of the good Guernseys were in Southern Wisconsin, they went away with different ideas. The service bulls are Guydette, whose dam, Yeksa's Queen made 599.8 lbs. of butter in a year.

This is perhaps the largest bull of the breed, weighing in fair flesh, 2,100 lbs., and not at all coarse, even with this size.

Another is Buckthorn, whose dam, Queen of Chenequa, made 512 lbs. butter for Mr. Solveson, and her dam was the well known cow Fantine 2nd that made 602.7 lbs. butter. Another is Treynore, a bull that was first prize at the Wisconsin State Fair, and out of Tricksey 3rd who, and her dam as well, were both first prize winners at the same show. Mr. Rietbrock has also coming on a fine young bull in Paxtang, a son of his cow, Elloree of Paxtang, purchased last year at a large price from Miss Wilhelm of Pa. This young bull was sired by the well known Glenwood Boy of Haddon, whose dam, Glenwood Girl 2nd, made 593.5 lbs. of butter in a year.

Mr. Rietbrock also maintains a good herd at Glyndwr Farm near Portage and uses there, Benign, a son of Benjamin, and Preston, 441 lbs. He has many extra good cows, most of them being daughters or granddaughters of Yeksa's Prince, who like most of the bulls was sold before his value was known. One of these, Yeksa Sunbeam was milking 47 lbs. of milk that the manager said was testing 4.3% fat. A number of others have milked above 40 lbs., and one up to 54 lbs. per day. The whole herd are very uniform and have splendid udders and teats.

Among the best ones not of the Yeksa family are Elloree of Paxtang mentioned above, a Madame Patti, a daughter of Benjamin, and Lindenora, a daughter of Lily Ella's Jeweler. After a rousing vote of thanks to Mr. Rietbrock. we separated from what had been the greatest meeting ever undertaken in this line among dairy cattle breeders. GEO C. HILL.

A Short Talk on Improved Large Yorkshires.

ED. HOARD'S DAIRYMAN:—The present era of wonderful prosperity for the farmer offers long sought opportunities to replace the mongrel with pure bred registered stock, which will not only bring largely increased profits in open market but enable the careful breeder to dispose of surplus choice animals at advanced prices, to others also having in view the bettering of their financial condition; and in this most commendable transformation the pig has received his full share of attention.

This is because no other live stock will so soon bring profitable returns on the investment. Pigs and prosperity go hand in hand, and the farmer without them is poor indeed.

It is true that some farmers who have had a round or two with hog cholera have decided that there is no money in pigs; and, without endeavoring to locate and correct the trouble, have gone out of the business. Others have refused to yield and have persistently bent their energies toward overcoming the evil; and it is to those, whose pluck, perseverance and research, brought first from England to Canada and later to the United States the Improved Large Yorkshires that all lovers of the choicest product of the pig are deeply indebted.

A glance at a thoroughbred Yorkshire cannot fail to impress one with the thought that an animal so constructed, with a long, deep, well-boned frame, must surely yield the largest possible percentage of high price meat in the form of well streaked bacon, and that the absence of excessive fat about the neck and throat must indicate far less liability to cholera and kindred diseases than the square, blocky and excessively fat specimens of other varieties which we have for years been taught to admire at the fairs and stock shows.

Statistics, and the experience of breeders and packers, have fully demonstrated that these cases of "Love at first sight" are amply justified.

In Canada few other than Yorkshires are bred for the packing house trade, and as nearly all their output of bacon is exported to England and sold at top prices, Canadian farmers are paid from one dollar to one dollar and fifty cents per hundred pounds more for Yorkshires than for other varieties. The American palate is as sensitive to good things as is that of our English cousin, and as a consequence the demand for Yorkshire breakfast bacon has so rapidly increased, that packing houses in the West have distributed by the car load, boars of this excellent breed, among the extensive pig raisers from whom they draw their supply.

The demand is not for lard, the price of which must always be regulated by that of cottolene and other substitutes, but for lean meat of exquisite flavor and tenderness, of which the Yorkshire has at the present time an apparent monopoly.

If comparative freedom from disease and the superior quality of meat were the only advantages possessed by the Yorkshires, they would be sufficient to convince most investigators of their true merits, but when we add to the good points mentioned those of great prolificacy, gentle disposition, and ability to properly suckle and raise large litters of rapidly maturing pigs, it would appear to the most sceptical that as a money earner the Improved Large Yorkshire stands in a class by itself.

Yorkshires are white, and so strong is the paternal influence in breeding that the writer has never seen a black spot on a pig from a Yorkshire boar, even though the dam were a Berkshire or Poland China. White pigs are preferred by the butchers and packers, hence the value of Yorkshire boars in improving herds of other varieties. W. H. FISHER.

Columbus, Ohio.

THE BROWN BESSIE HERD Offers one bull 14 months old, sired by Recorder, 29239, the only living son of Brown Bessie and has 14 tested daughters. Dam, Relay, 70353, test 17 pounds 2 ounces. She a daughter of Diploma with 61 tested daughters. Also Berkshire Pigs of English and American selected stock. H. C. TAYLOR, Orfordville, Wis.

Money to Waste on Aquatic Creamers, but None to Invest in Profitable Reading.

An Alfalfa Query from Maine.

ED. HOARD'S DAIRYMAN:—You probably think I did not try to get a club for your most valuable paper, but I did, and failed completely. Could not find any one at our local Grange that could afford it. One of the patrons cannot afford the DAIRYMAN and of course cannot purchase an effective cream separator, but uses one of those aquatic affairs. One man, whom I urged to put a quarter in a mailing card last year, had money to invest in the same way. We are really in a bad way here, butter fat, 22c; bran and corn meal have been about $1.50 per hundred and cotton seed $1.80, the past winter. Just starting in silos. I am afraid we have not much alfalfa land, too wet and heavy. I would like your opinion and advice about a piece of land; I plowed part of an old pasture last fall, late, some parts were wet, so I turned a deep furrow across the end and through the middle, and it seems to be gravelly. Do you think it advisable in this climate, almost Aroostock county, to drain it and try alfalfa? The land lies fine to drain. It slopes to the south and also to the west, and forest on the west. If drained how deep had I ought to dig? Would have to hire it done, wages one dollar or more and board a day. No surplus capital and a large family

DOWN EASTER.

Penobscot Co., Maine.

Reports of the character submitted by this correspondent concerning the attitude of his neighbors towards improvement in dairy husbandry are discouraging and at times almost disheartening. What is the use, we are tempted often times to say, of trying to help those who show no disposition whatever to help themselves? Why not let them wallow in the mire of their own ignorance? However, with us, it has always happened that when about on the point of giving up, there will come in reports of a different character, reports bearing abundant testimony that we are not living and laboring altogether in vain, but in some measure at least, are helping on to better things, to higher life, greater comfort, a very considerable number of our fellowmen, and there is a satisfaction in that which nothing in the way of dollars and cents can measure. And so, we say to Down Easter, "Do not be utterly cast down and disheartened." Sooner or later, some of his neighbors, taking note of his methods and comparing them with their own, will be inclined to ask "why the difference" and join him in the march upward and outward to better things and larger hopes.

No one can tell in advance whether alfalfa will thrive under the conditions named. Only a few years ago, it was assumed that it was useless to try alfalfa in Wisconsin, that it would only thrive in the warm and semi-arid regions of the West and Central West, but at the present time, the question is not so much where it will thrive as where it will not thrive. So far as present experience has gone, about the only condition which seems fatal to alfalfa prospects is the presence of soil water too near the surface. In the present state of knowledge on the subject, it is not safe to advise anyone to try to raise alfalfa on land where standing water comes within eight feet of the surface. Of course, surface drainage is indispensable, that is to say, water standing on alfalfa from thirty-six to forty-eight hours, is pretty sure to kill it.

It would not be prudent to undertake to tile-drain land for alfalfa as it would be almost certain to send its roots into the drains and clog them up. If our friend can, by a system of shallow, open ditches, dispose of the surface water on this field and the permanent soil water does not come within ten feet of the surface there would seem to be no reason why he might not expect fair crops of alfalfa.

GREATEST OFFERING OF

HOLSTEIN-FRIESIAN CATTLE.

McADAM & VON HEYNE'S

Justly celebrated herd, will be sold at Public Auction, at the home of the World's Champions, at Brothertown Stock Farms, Deansboro, N. Y.,

WEDNESDAY, MORNING, JULY 15, 1903

This sale includes every animal in our herd. Sadie Vale Concordia, the World's Champion, with official record of 30 lbs 10.2 oz. butter in seven days, one of her sons, now 3 years old, 2 daughters, 5 granddaughters, 1 grandson and 2 great granddaughters and sons, will go to the highest bidder. **Mercedes Julip's Pietertje,** the famous ex-champion with official record of 29 lbs. 5.3 oz. butter; her daughter and granddaughter will also be sold. Another great offering in a sire is **Canary Mercedes Johanna De Kol,** out of Canary Mercedes Brightest with official record of 21 lbs. 3 oz. at an age of 2 years and 11 months, and by Johanna Rue 2nd. Paul De Kol, who has now 13 in the Advanced Register. The four nearest dams average 23 lbs. 5.6 oz. butter in official test. They average 4 6 per cent fat. This includes record of dam made in two year form. Herd numbers

70 HEAD OF VERY SUPERIOR ANIMALS,

selected with great care. A large number being from the CELEBRATED YEOMANS HERD. All cows offered are in calf, either by Sir Pietertje Posch, a son of Alta Posch, with official record of 27 lbs. 1.4 oz. butter at 2 years and 11 months, or by Sadie Vale Concordia's Paul De Kol. or by Canary Mercedes Johanna De Kol. In this offering of fine stock are cattle suitable for the best herds, also for the improvement of good herds, as well as cattle for the beginner; as the latter, in buying any of these cattle will start right, which is an important part of the success of breeding pure bred cattle. Farm can be reached on the D. L. & W. to Waterville, N. Y., or the O. & W. to Deansboro, N. Y. Trains will be met promptly and visitors conveyed to the farms. Also farms can be reached by trolley from Utica to Clinton, thence by livery. Catalogues ready early in June. Address

McADAM & VON HEYNE, Deansboro N. Y.

The sale will commence promptly AT 10 A. M. WEDNESDAY, JULY 15, 1903.

High Class Advanced Registry Stock only. Best butter families. Stock for sale.

Woodside Farm, Princeton, Worcester Co., Mass. JOHN B. MARCOU.

T. G. YEOMANS, strain of H. F. Cattle, nearly the same breeding of Sadie Vale Concordia. Waynes Aaggies, Netherlands, Americas, Pauline Pauls and De Kol Bulls old enough for service, and Bull Calves for sale.

Wm. O. Jackson & Sons, South Bend, Ind.

LOOK HERE.

34 cows and heifers in the McGEOCH HERD have been officially tested with the following results: 10 cows average 20.26 lbs. butter in seven days; average per cent of fat 4.06. 7 four-year-olds average 16.82 lbs. butter in seven days; average per cent of butter fat 3.93. 9 three-year-olds average 15.06 lbs of butter in seven days; average per cent of fat 3.50. 8 two-year-olds average 12.16 lbs of butter in seven days; average per cent of fat 3.60. We have a few young bulls out of some of these cows, and sired by Gem Pietertje Hengerveld Paul DeKol, or Sir Ormsby DeKol for sale. One of these is out of a cow that made official record of 24.88 lbs. of butter in seven days, average per cent of fat 4.47. Are these the kind of Holstein-Friesians you wish? If so, can we not interest you in putting a bull from this class of stock at the head of your herd? McGEOCH HERD is located at Lake Mills, Wis., 56 miles west of Milwaukee. For particulars address H. B. Daggett, Mgr., Station A, Milwaukee, Wis Residence: National Ave. near 40th. Phone, South 1601

PUBLIC SALE OF FAMOUS CATTLE.

Current advertisements in this paper, announce a dispersal sale at auction, July 15th, 1903, of the Brothertown Stock Farms herd of Holstein-Friesian cattle. This herd is the home of the two cows, Sadie Vale Concordia and Mercedes Julip's Pietertje, who stand at the head in the list of officially tested Holstein cows. These and others like them are included in the sale catalogue, in company with males of choicest breeding, including a son of Sadie Vale Concordia.

Well may the proprietors, Messrs McAdam and von Heyne, say that a sale of this character will be an "occasion of rare interest for the Holstein-Friesian world," and that it offers "a fine opportunity for breeders to improve their herds with a new addition of most fashionable breeding," and that the "beginner has also a chance to select a foundation herd of the most noted families and combinations.

A FARMER BIGGER THAN HIS FARM.

Travel where you will through the farming districts in any state, a moment's glance is only needed in passing a farm, to see whether the farm or the farmer is the bigger. Old Sam Evans, a quaint New Yorker, used to illustrate the men who were smaller than their farms, by the story of the old sow which had eleven pigs when she had only eight places of nourishment. Uncle Sam said: "She had oversized herself."

But here is a case related by Prof. Weld, of the New Hampshire Agricultural College, where the farmer was bigger every way than his farm. Prof. Weld says:

I have in mind a young and successful New Hampshire dairyman, a graduate from our four years' agricultural course who, after graduation, returned to his father's farm and in due course of time has established for himself a herd of thirty pure bred Jerseys. He began this work with one cow and has steadily followed the plan which he adopted before taking up that work. Eventually the father retired, selling to the son the ancestral acres. Steadily and surely the young man has continued, gradually increasing the size of his herd, and increasing the individual productive capacity of the cows at the same time. Last year the thirty cows, every one of which was bred and raised on the farm, averaged him 340 pounds of butter per cow. Should you meet him to-morrow he could tell you just the amount of milk and butter each one of those thirty cows produced, as well as the cost of food required to produce it. He makes his own butter on the farm, using the skim milk and buttermilk in raising his young stock and pigs. His farm is one of those side hill farms, such as are often found in New Hampshire, but it is a model of neatness and one can but feel a higher regard for agriculture and dairying as a business, after having inspected its various departments.

Does Casein Affect the Keeping Quality of Butter.

It has heretofore been held by experts in dairying that one of the reasons why butter from which the casein, or nitrogenous part of the milk, has not been completely removed in the process of washing is more liable to become rancid or develop strong flavors more readily than butter which has been thoroughly washed, is because the casein or nitrogenous matter thus left behind undergoes rapid decomposition, and therefore injures the keeping quality of the butter. With the object of putting this matter to a test, some interesting experiments were carried out last year in connection with the dairy department of the Ontario Agricultural College. The question which it was the purpose of these trials to answer was: "Does the amount of nitrogenous matter in butter affect its keeping quality?" For the purpose of the trials a number of samples of butter, churned in different ways and washed with different quantities of water, were carefully analyzed for the purpose of determining the proportion of nitrogen present in them. Other samples of the same butter were carefully put by and kept for a certain length of time, at the end of which they were examined and graded according to their quality. So far as the experiments went, the results showed that the presence of more or less nitrogenous matter in the butter did not materially affect its keeping quality. The proportion of nitrogen present in the majority of samples ranged from .076 to .090. Curiously enough, some of the samples which contained the smallest proportion of nitrogen were those which kept worst, or rather were of the worst quality at the end of the three months. The sample which scored the highest proportion of marks was made from milk separated at 180 degrees Fr., and containing .079 of nitrogen. Another sample which scored very high was washed with brine, and contained .085 per cent of nitrogen, whereas a third, which contained only .079 per cent of nitrogen, and was made from milk kept in shallow pans, scored the lowest of any of the samples.

We append a table showing the results obtained with the various samples tested.

DESCRIPTION OF BUTTER.	*Average per cent. of Nitrogen.*	*Average score at end of 3 months. Max.- 100.*
Butter washed with brine...	0.084	91.
Butter washed with water...	0 085	94.
Butter made from cream separated at 90 degrees F...	0.070	92.5
Ditto, at 140 degrees F.....	0.087	92.3
Ditto, at 160 degrees F.....	0.091	93.8
Ditto, at 180 degrees F,.....	0.079	94.75
Milk set in shallow pans.....	0.079	73.
Milk set in deep vessels. ...	0.083	87.

Dollar-a-Day Cows!

A Reply to John Gould.

ED. HOARD'S DAIRYMAN:—In your issue of May 29th, page 364, column 2, is a clipping from an article written by myself and published in the columns of the *National Stockman and Farmer* followed by a criticism by one John Gould, to which I beg space to reply.

First, the criticism is unfair, the statement never was made that the cow would give 5½ to 6 gallons of four per cent milk, ten months in the year; but I have grade Short-horn cows in my barn that in ordinary flesh will weigh 1200 lbs. and have given during the winter months, January, February and March, 5 to 6 gallons of 4 per cent milk, and which made me one dollar per day, shipped to the city market. Now I am no scientific dairyman or teacher or enlightener. I am a plain, practical farmer and milk shipper; have had 60 years' experience, and that experience is my teacher; and I lay more stress on the individual cow, than on any family, breed, fad or fancy in cows, and I care nothing about Mr. Gould's nervous theory, incurving thighs or his pelvic arch. I don't care if she looks like a hyena, camel or buffalo, if she does her work at the pail, that is her passport and her bill of particulars.

With regard to the "if" Mr. Gould refers to, I have frequenty had these kind of cows lose their usefulness in my dairy on account of not breeding, and of course then they would go to the butcher.

Now what I have written concerning this matter does not seem so wonderful or so deserving of ridicule as it seems to this facetious Mr. Gould. There are other men a plenty in this vicinity (we are all farmers and milk shippers) who are doing as well with their herds of common or grade cows, or scrubs, as the breeders call them, as I am. And if Mr. Gould will come to Export, it is 20 miles east of Pittsburg, on the P. R. R., I will bring him to my farm, and try to convince him that this is no fancy tale; and will also show him a field of wheat that is hard to beat even by a Buckeye.

Export, Pa. JOHN G. FOIGHT.

Pig Feeding.—Rotation of Crops, Etc.

ED. HOARD'S DAIRYMAN:—I am feeding some pigs about 2 months old. I want to give them equal weights of shorts and ground or soaked corn mixed with about all the separator skimmed milk that they will drink. What I want to know is, what price ought whole ear corn to be, to be equal to hominy meal at 90 cents per cwt? What is the per cent of gain made by grinding corn for pigs?

I have about 50 acres of tillable land and no permanent pasture. Is there a better rotation of crops than the one I am following, viz.: Corn, oats, wheat, clover and timothy for meadow, clover and timothy for pasture?

Would there be any gain or loss by plowing sod for oats, then follow with corn, and then sow wheat on corn stubble without the work of breaking the

National Dairy Machine Co., Newark, N. J.

Reid's Hand SEPARATOR

The "best" separator is that one which does its work most thoroughly and easily, that is built of strongest material, and that is most easily washed and kept in order.
First cost is a great point with a buyer, but ease of running, perfection of skimming and simplicity in washing are even greater considerations.
The **Reid Hand Separator** has but a single cylinder inside the bowl, and skims as closely as one-hundredth of one per cent. Indeed, some tests indicate "not a trace" of fat in the skim milk.
The Reid is perfectly planned and strongly built, and it literally "runs like a watch."
As to our guarantee of excellence, we make the strongest statement that can be expressed in words: **Money back (less freight) if the buyer is not satisfied.**
There is a new (free) booklet about the Reid Hand Separator.
Sizes run from 150 lbs. to 500 lbs. per hour.

ground? I spread all the manure on the land for corn and use all the wheat to buy shorts for pigs and bran for cows.

Will this rotation of crops build up the soil, or impoverish it? Am I on the right track?

Your paper is quite an encouragement to me. I feel that I have learned more about dairying from it and the experience I've had since I commenced taking it, than I knew before I commenced taking it. N. P.

Bloomingdale, Ind.

Experience has demonstated that the most profitable way to feed young pigs is to use not more than three to five pounds of skim milk with each pound of middlings or ground corn. Probably, well soaked and softened corn fed in the same proportion might serve an equally productive purpose, although, for very young pigs, we should prefer the ground feed. We cannot advise feeding corn and cob meal to swine and especially to young swine. The pig has a comparatively small stomach and, therefore, does not require bulky food and cannot handle it to good purpose.

Hominy meal contains approximately 88% of digestible nutrients and ground corn 84%, but for feeding with skim milk, we do not think there would be anything gained by using the hominy meal in preference to ground corn.

The present system of rotation is possibly as good as any that could be adopted and it is very doubtful whether any gain would result by changing the first crop on sod-plowing from oats to corn. It is coming to be believed that the better way to handle manure is to spread it on grass land and not plow it under. This, of course, necessitates comparatively light manuring, but it insures a greater development of the grass for hay or pasture, and what is equally important, a larger development of the root system, thus adding materially to the humus in the soil, a matter which receives altogether too little consideration.

Thanks for the compliment to our paper. The accumulation of evidence of this character continually incites us to spare neither labor nor expense in the endeavor to make a journal worthy of the continued confidence, support and respect of its tens of thousands of readers.

Dairy Breed Test.

At the Maine Experiment Station Holsteins, Ayrshires and Jerseys were tested during a period of two years on the following points: 1. The amount of food and nutriments. 2; Yield of milk solids, fat, cream and butter, and the combination of the whole milk, skimmed milk and butter milk.

Results—The average amount of water free food consumed daily, for each animal, was Holsteins, 27.4 pounds; Ayrshires, 24.7 pounds; Jerseys, 23.3 pounds.

The annual yield of milk solids was Holsteins, 1,014 pounds, Ayrshires, 848 pounds; Jerseys, 827 pounds; and of butter fat, Holsteins, 285 pounds; Ayrshires, 233 pounds, and Jerseys, 297 pounds. Milk required for a pound of milk solids, Holsteins, 8.3 pounds; Ayrshires, 7.8 pounds; Jerseys, 6.6 pounds; for a pound of butter fat, Holsteins, 29 4; Ayrshires, 28.3; Jerseys, 18.3.

3. The cost of a quart of milk, reckoning the cattle foods at market prices was: Holsteins, 1.83 cents; Ayrshires, 2.03 cents; Jerseys, 2.42 cents. The food cost of a pound of milk solids was for Holsteins, 7.09 cents; Ayrshires, 7.45 cents; Jerseys, 7.44 cents; of a pound of butter fat, Holsteins, 25.22 cents; Ayrshires, 26 62 cents; Jerseys, 20.43 cents.

The average composition of the milk for the two years was: Holsteins, solids 12.22, fat 3.47; Ayshires, solids 12.98, fat 3 67; Jerseys, solids 15.24, fat 5.50.

The loss of fat in the skimmed milk was least for the Jerseys. Solids of skimmed milk were: Holsteins, 9.50 per cent.; Ayrshires, 10.40 per cent; Jerseys, 10.50 per cent.

People Buy Butter by the Nose.

They may also taste it, but if it does not smell sweet they are not likely to do so. Your butter may suit the public nose exactly when it leaves your dairy or creamery, but how about it at the end of a week's handling by other parties? Is it not wiser and better for the butter and your reputation to so pack it that neither will be endangered? You can make sure of these points by wrapping every print in a sheet of our

Pioneer Brand Parchment Paper.

It will keep that rancid lot close by from spoiling yours. It keeps out all destructive germs and injurious odors and entirely preserves all the flavor and natural sweetness. It makes fastidious buyers want more of your butter. You see we print your name, name of dairy or creamery or other private trade mark or brand on every sheet. It helps to build a reputation for your butter. Just think these things over and then write us for samples of paper and booklets. **Be sure to ask for our booklet, "Better Butter."** We mail these free.

The Paterson Parchment Paper Co., 37 Eighth St., Passaic, N. J.

Testing Cows in Scotland.

Report on the Benefits Derived by a Systematic Test and Weeding out of Poor Cows—Production Increased One-Third and Over.

Farmers who keep cows for milk production, should be sufficiently interested in their dairy investment to make that investment pay the largest possible dividends. How it is done in Scotland, with comment on other systems, appears in a recent report by John Speir of Newton Farm, Glasgow, which report in part reads:

"For a long time back it has been customary in this and other countries for persons taking a particular interest in their cows to regularly weigh the milk of each animal. A very few people did so morning and evening, but the bulk of those who kept milk records, and their number is very small, contented themselves by doing so once a week or once a month. Where cows are kept, the busiest hour of the day is usually that of milking; the consequence is that, although most breeders are cognizant of the gain to be derived from a milk record, only an enthusiast undertakes the trouble.

Twenty years ago, when I first made a tour of Danish farms, I was greatly impressed with the number of average farmers who methodically weighed the milk of each cow night and morning. Few people are so methodical in their habits as the Danes, and none have learned and appreciated so highly the value of a milk record as they have done. The enthusiasm and methodical working of the Danes were not, however, proof against becoming tired of such work. A more satisfactory way had, therefore, to be discovered and this work has now almost entirely fallen into the hands of small societies, which undertake the work for their members.

These societies, as a rule, are composed of from ten to twenty farmers (twelve is considered the most suitable number) who own among them from 200 to 400 cows. Each society becomes affiliated with the Royal Danish Agricultural Society, and through them get from the government a grant ranging from one-third to one-half of the total expenses. The society then engages a young man, whose duty it is to spend a day at each farm, weigh and test the milk of every cow, and during the winter also weigh the total quanitity of food of each class given to the cows for one whole day. It is the duty of each member to board and lodge the young man while at his farm, and convey him and his weighing machine and milk tester to the next farm when finished

One person can weigh the food, and weigh and test the milk of any number up to fifty cows in one day, and, being constantly at it, becomes more expert, and does it more reliably than the ordinary farmer. The results for each farm are all tabulated by the parent society, which forwards a copy of the results to every member. Each member contributes in proportion to the number of cows tested, dry cows being left out of the account. According to Danish labor, the cost works out at about ¼d per cow for each double weighing and testing of the milk and weighing of the food used.

As a rule, the visits are made every fortnight, but in some cases every week, and others only once a month.

The first societies were begun in 1895, and the number at the present time is over 300. The work is very popular with the average farmer, as he finds he gets many hints as to cheapening cost of production. Some farmers are found to produce a gallon of milk or one pound of butter at two-thirds of the cost of others, and some herds to produce one-third more than others.

Comparing the Danish records of the first and last years, it seems that the average milk yield of each cow has been increased nearly ½ per cent per annum, while the percentage of fat has also been somewhat improved. This result, which in time will amount to an immense gain, has been brought about principally by breeding from the best milkers, and getting rid of the bad ones. The gain in the seven years under review seems steady, and appears likely to be maintained for a considerable time to come.

This system has rapidly spread over both Sweden and Norway, the latter country, owing to the greater variety in the size of its herds, adopting a slightly different system of membership. In Norway, each member, besides keeping the weigher for a day and paying the cost in proportion to the number of his cows, pays an arranged-on sum as an entrance fee.

This system of methodically weighing and testing the milk has brought to light numerous instances of families of cows which produce double the milk that the average animal does, and in some cases even more than that. Many instances are also discovered of cows which do not give sufficient milk to even pay for their keep. One notable instance may be mentioned among many, of a cow which for fifteen years has averaged over 1,400 gallons of milk per annum, or over six tons of milk each year. This cow gives milk of fair average quality, and several of her progeny seem as if they would equal, if not excel, her milk yield. The red Danish cow is a little larger than the average Ayrshire and smaller than the Short-horn, the live weight running from 8½ to 9½ cwt.

The following may be mentioned as instances of what can and has been done by selection of good milking types:

Mr. Tisdall, when he began business, bought twelve of the best heifers he could get, and continued to breed from the best of these for twenty years. The average yield of milk the first year was 456 gallons, the tenth year it was 600 gallons per heifer, the twentieth year 868 gallons per heifer for twelve. By the same process, Mr. Evens, Burton, Lincoln, had the following: For three years to 1893, his cows averaged 751 gallons; for three years to 1896, his cows averaged 811 gallons; for four years to 1900, his cows averaged 861 gallons. An increase of 110 gallons in ten years. Mr. Evens has one cow, Beauty, which, after her third calf, gave 2,051 gallons in eighty-one weeks; after her fourth calf, 1,622 gallons in fifty-two weeks. Burton Old Profit has given an average of 1,200 gallons for seven years."

A New Way of Fattening Poultry.

Armour & Co., of Chicago, have established a large poultry fattening establishment, at Marshalltown, Iowa.

The method employed is a most novel one, and has been tried in the east with great success. The old theory that: "You can lead a horse to water, but you cannot make him drink," has been exploded so far as live poultry is concerned. By the new process they not only lead the chick to the feed, but they also force him to take it into his interior, and, best of all, he fattens on it. The chickens are fed one at a time by machinery. The food used is especially prepared, and is composed largely of cereals. It is in liquid form and is forced into the fowls through the bill by a high pressure. As soon as they are fed, the fowls are put in a dark room, so that they will not, by running around, lose their flesh. They are kept in this room excepting during the feeding time. Ten days are all that are required to make what was a poor, lean chicken a plump, fat fowl.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN: —Butter went up a half notch on the Board of Trade to-day and is now quoted at 22 cents firm. The output was 828,000 lbs. New York was reported steady at 22½ cents, with receipts of 11,612 lbs.

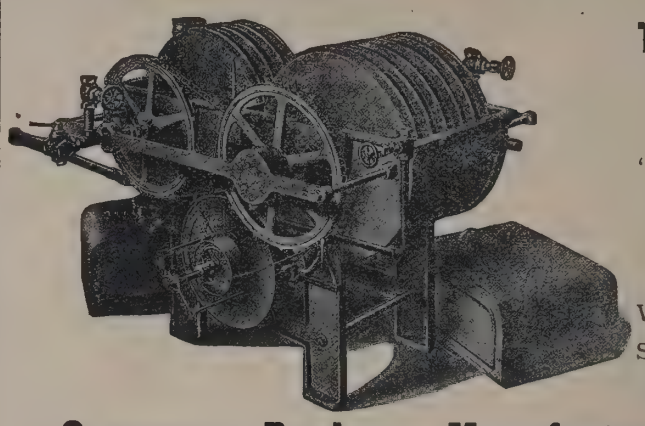
CONCERNING OUR ADVERTISERS.



SHREDDED FODDER.

About one half the feed value of the corn crop is in the stalks, and wherever this fact is thoroughly understood the corn grower considers it just as important to shred the fodder as to husk the ears. If the stalks are allowed to stand in the field until after the corn is husked, the fodder has little or no value as feed stuff, and this explains much of the misinformation that is still extant relative to shredded fodder. Neither timothy nor clover would make good feed if allowed to stand too long before cutting. If, however, the corn is cut at the right time, the fodder when shredded makes excellent feed, which analysis shows to be fully as nutritious as timothy hay. The McCormick husker and shredder enables the farmer to husk and shred his corn at one operation, thus saving time as well as all of the corn, and practically doubling the value of the crop.

CORN IS KING.

If you raise corn you need to use the latest and most approved appliances, not only for cultivating the crop, but for harvesting it as well. We cannot urge our readers too strongly the importance of investigating the merits of the Badger Corn Har-

Did You Ever Keep a Record Of Your Cows?

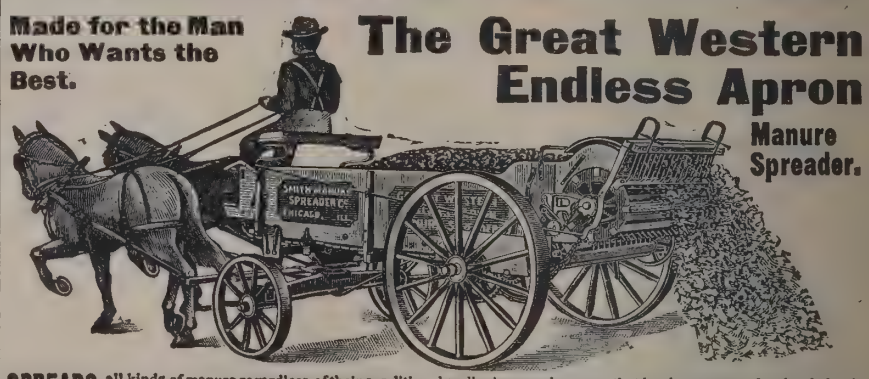
IF SO, you have felt the need of a convenient, simple and handy Record Sheet. We have had so many requests for these Record Sheets that we concluded to get up one that would "fill the long felt want." We have a very simple and complete Record Sheet for 10 cows, one month, that is printed on heavy Manilla Paper, we can send postpaid at following prices:

Price 5c Each | 6 for 20c | 12 for 30c | 25 for 50c

SIZE 10x16 INCHES

We also have a one cow Record Sheet, heavy Manilla paper (one month) that we will mail postpaid

Single Copy 5c | 5 for 15c | 10 for 25c | 25 for 40c



SIZE 6x15 INCHES

HOARD'S DAIRYMAN.

FORT ATKINSON, WIS.

Made for the Man Who Wants the Best.

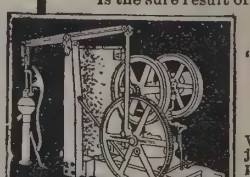
The Great Western Endless Apron Manure Spreader.

SPREADS all kinds of manure regardless of their condition, handles barnyard manure that has been tramped so hard that it is necessary to loosen with pick, fresh stable manure, containing wet or dry straw, corn stalks, etc. Old straw stack bottoms, whether rotted or not. Cow manure fresh from the gutter, sheep manure, lime, salt, ashes, and in fact all kinds of manure and fertilizers and does it quicker, better and more evenly than by hand. Spreads as much manure in one day as 15 men can by hand. Spreads the largest load in 2 to 4 minutes. Makes the same amount of manure go three times as far and produce better results. Every machine has our NON-BUNCHABLE RAKE which forms a hopper and holds all hard chunks of manure in contact with beater until thoroughly pulverized before discharging, therefore no bunching or uneven work. The ENDLESS APRON is one continuous apron (Not a ½ apron) and therefore is always ready to load, no turning back into position with crank or reverse gears to cause breakage. Apron does not extend below axle. The Combined HOOD AND END GATE keeps manure away from beater while loading, prevents choking of beater when starting and acts as a hood and wind shield in spreading. Starts the manure in the right direction, therefore spreads more evenly. **It has a graduating lever and can be regulated to spread thick or thin 8 to 25 loads per acre while in motion. It catches the poor spots with a double dose.** LIGHT DRAFT 1st. Because the load is nearly equally balanced on front and rear wheels. 2nd. The team as near load as it can work. 3rd. Front and rear axles are same length and wheels track. 4th. Beater shaft runs in a **ball and socket bearing,** therefore no friction. **Beater** is 23 inches in diameter. Has a shipper that **positively** throws machine into and out of gear and holds it there. STRENGTH AND DURABILITY. Our machine is **Seat** turns over when loading. Machine turns in its own length. made so strong that it is almost impossible to break it. Every piece is made extra strong regardless of cost. Every gear and sprocket wheel is keyed on. We use no pins or cheap crontrivance to come loose, get out of order, break and cause trouble. GUARANTEE. Should any part break, wear out, or get out of order within one year, we replace free of charge. LARGE CATALOGUE 10 by 13 inches, with 8 large cuts shows spreader perfectly and describes it fully. Gives 34 reasons why the **Great Western Endless Apron Manure Spreader** is the best and most complete machine made and why you should have one. Also tells how to apply manure to secure best results. **Mailed free.**

SMITH MANURE SPREADER CO., 59 N. JEFFERSON ST., CHICAGO, ILL.

BLIZZARD

Safe, Strong and Efficient.



Cuts and Shreds all kinds of Dry and Green Fodder and elevates it to any desired height through a PNEUMATIC TUBE. No sprocket, no link belt, no elevator buckets, web, slats, etc. **Saves power, breakage and annoyance.** It cuts various lengths; **any capacity you want.** Call at your dealer's and examine it or write us for circulars and descriptive matter, &c

vester, as manufactured by I. Z. Merriam of Whitewater, Wis. See ad in another column.

WHY COWS SHOULD BE PROTECTED FROM FLIES.

Every thinking farmer and dairyman knows that if he protects his cows from flies during the hot days, they will give in return a larger quantity of milk and gain instead of losing flesh. Then there is also to be taken into consideration the fact that when cows are thus protected during fly-time, there's no difficulty experienced in milking—no irritable cows, with their continual whirling of tails. A stock protector that is having a large sale just now, and which is claimed to be the best manufactured, is familiarly known as "Shoo Fly." This wonderful protector of cattle in fly time is a harmless liquid that not only keeps flies away, but kills all that come in contact with it. Cures all sores, scratches, skin diseases, hoof ailments, etc. "Shoo-Fly" is for sale by most all dealers, but if for any reason it cannot be obtained, send $1.00 to the Shoo-Fly Mfg. Co., 1005 Fairmount Ave., Philadelphia, Pa., and get in return the latest improved three-tube sprayer and enough "Shoo-Fly" to protect 200 cows. If it does not do what is claimed for it, money will be cheerfully refunded.

BROTHERTOWN STOCK FARM SALE.

In the advertising columns of this issue will be found the second announcement of the public sale of the celebrated Brothertown Herd of Holstein-Friesian Cattle. This sale will be an occasion of rare interest for the Holstein-Friesian World. We believe there was never a more propitious time for breeders to add worthy animals to their herds, and we trust that a large delegation will attend the sales.

The sale will be held at the home of the World's Champions, at Brothertown Stock Farms, Deansboro, N. Y., July 15, 1903, and will commence at 10 a. m. sharp. The farm can be reached over the O. & W. to Deansboro, N. Y., or over the D. L. & W. to Waterville, N. Y., or on the street car from Utica to Clinton, N. Y. Visitors will be met at trains promptly and livery can be obtained at Clinton to get to the farm.

The first animal in the catalogue is Canary Mercedes Johanna DeKol, a sire of great individuality and choice breeding, now in his two year form. His dam is the great heifer Canary Mercedes Brightest, with official record of 21 lbs. 3 oz. butter in seven days at an age of 2 years, 11 months. Her average test being 4.34 per cent butterfat, and his grandam is the great cow, Canary Mercedes, with official record of 25 lbs., 2.6 oz., butter and average test of 4.96 per cent butter fat. He is sired by Johanna Rue 2nds Paul DeKol who has now 13 daughters in the Advanced Register and his dam is Johanna Rue 2nd, with official record of 21 lbs., 4.5 oz. butter in seven days, and his granddam is Mutual Friend 2nd, with official record of 25 lbs. 12.2 oz. butter in 7 days. The average production of his four nearest dams is 23 lbs., 5.6 oz. butter, and they aver age over 4 per cent butterfat.

The Mercedes family is too well known by the high percentage of butter fat and the get of the above bull will speak for itself.

Canary Mercedes Brightest 2nd, a full sister to the above sire, is a well proportioned heifer and in calf to Sir Pietertje Posch, a son of the famous heifer, Alta Posch, with official record of 27 lbs. 3 oz. butter at an age of 2 years 11 months, this being the world's record for 2 and 3 year-old cows. Two of the most attractive numbers of the catalogues are Sadie Vale Concordia, the world's Champion butter cow with official record of 30 lbs. 10.2 oz. butter in seven days, 123 lbs. 10.7 oz. butter in 30 days and 220 lbs. 8 4 oz. butter in 60 days, and Mercedes Julip's Pietertje with official record of 29 lbs. 5.7 oz. butter in seven days. Mercedes Julip's Pietertje will be fresh in about 12 days, and she will be in fine condition at the time of sale.

Both cows are too well known to enter into details of their breeding, both have added new glory to the breed, and undoubtedly many new admirers and friends have been won over by the great performance of those two noble animals.

A son of the World's Champion, Sadie Vale Concordia's Paul DeKol, is also another attraction. He is a fine, vigorous bull, 3 years old, very straight and a fine handler. He is sired by Paul De Kol 4th, and was bred at the well known Yeomann's herd. The average production of his 11 nearest dams, mostly tested by Messrs. Yeomanns, is 23 lbs. 6 oz. butter in seven days. This includes the record made by his granddam at an age of 22 months. All other cows in his pedigree average over 20 lbs. butter per week. A half sister of Sadie Vale Concordia, sired by Paul DeKol, is also offered. This sale includes 2 daughters and 9 grand daughters of Sadie Vale Concordia, also a daughter and granddaughter and one prospective calf of Mercedes Julips Pietertje.

There is a number of very choice cows in calf to Sir Pietertje Posch or to Sadie Vale Concordia's Paul DeKol, or to Canary Mercedes Johanna De Kol, some of them with large official records, of fered. Also a number of very choice calves of both sexes, backed by large official records and by the best of breeding. Messrs. McAdam and Von Heyne have always used the best sires obtainable and have feared no expense of getting them. This sale is a fine opportunity for breeders to improve their herds with a new addition of the most fashionable breeding. The beginner has also a chance to select a foundation herd of the most noted families and combinations.

VETERINARY.

Queries in this department answered by DR. A. H. HARTWIG, Watertown, Wis.

Nymphomania.

One of my cows, to all appearances, is with calf, but seems to be in heat all of the time. C. M.
Wausau, Wis.

ANSWER.

This is a diseased condition of the clitoris which may be remedied by amputation of this organ. Employ a qualified veterinarian and have him make a thorough examination.

Sore Teats.

My cows have got sore teats and it is almost impossible to milk them; they crack open and bleed. The cows are out to pasture. Do you think they are caused by the cold winds? M. M.
St. Johnsbury, Vt.

ANSWER.

Traveling through wet pastures and pools of water by which the teats are immersed in the water or mud and afterwards dried by the air or wind is the usual cause. Wash the teats clean with soap and water and rub thoroughly dry, then apply glycerite of tannin, after each milking.

Selulitis.

I have a cow with sore eyes. Her eyes water and seem as if she has pus in them, and in the morning they are closed and has a time to get them open, and swollen good deal. The pus and water always run out of her eyes. The eyes seem to be sound otherwise. SUBSCRIBER.
Concordia, Mo.

ANSWER.

Bathe the eyes morning and night with camomile tea and add to each pint of the tea 10 grains of boric acid.

Unknown Disease.

One of my cows giving a good supply of milk came in heat, took the bull, was put into the barn during the day. The next day was in just as high heat. Kept in barn. Did not eat or drink anything, but bawled a good deal. Next day she was just the same and when turned out she wanted to jump on the cattle. When she stood and bawled she would fall down. Did not eat or drink and continued in that way, and when so weak she could not get up would bawl just the same, and finally died. A SUBSCRIBER.
Lone Rock, Wis.

ANSWER.

It would require a personal examination to ascertain the nature and cause of this disease. A post mortem examination would probably bring some light on the subject.

Milking from Six Teats.

A cow that milks out of six teats, the small ones on the back, makes it troublesome and also disaggreeable to milk her. W. H. T.
Melville, N. J.

ANSWER.

It is not advisable to milk the two little teats at all when she comes fresh. If you would not milk them from the start, they would not secrete milk and your extra work would be avoided.

Scabs on Teat—Abscess.

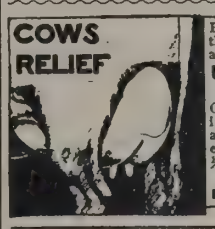
Several cows of the herd have sore teats. Begins with small scab, black. One swelled up and cracked open; the first one looked as if cut with wire fence. That one is well, having used creolin. The others do not respond to this treatment. Is it cow pox? Another cow at calving, retained afterbirth. I removed by hand; in a day or two she seemed lame in one hind leg. A swelling came just above the knee outside. Is not lame now. Could she have had milk leg and shall I have it lanced? F. W.
Hopewell Ctr., Pa.

ANSWER.

1. Wash the parts clean with soap and water after each milking, then rub dry and apply glycerite of tannin.

2. The enlargement appears to be an abscess. Have it lanced and keep parts clean thereafter.

Stringy Milk.



Have a cow that gives a sort of a gargety, or stringy milk, a'so bloats very easy when eating but a little grass. SUBSCRIBER.
Augusta, Wis.

ANSWER.

The condition of the milk together with the other symptoms are good evidences of indigestion. Give a complete change in diet, and a full dose of physic, small and frequent feeds of easy digestible food may be given; also give a tablespoonful each of powdered ginger and hyposulphite of soda, in food twice daily.

Horse Owners! Use
GOMBAULT'S
Caustic Balsam

A Safe, Speedy, and Positive Cure

RUPTURE CURED while you work. You pay $4 when cured. No cure, no pay ALEX. SPEIRS. Box 846, Westbrook, Me.

"Just as good?" "Just as good!" Did you say? "Just as good as Veterinary Pixine!!" The dealer who tells you that is mistaken. He does not know
FACTS AND TESTS PROVE IT!
Emery, Ky., April 9, 1903.
I feel it my duty to tell what Veterinary Pixine did for a horse of mine. He was cut with a knife between the fore legs three inches deep and two inches long, which every minute would gap open. I used several different kinds of remedy without success, even to having some stitches taken. Nothing did any good and it kept swelling and became feverish I almost gave up hopes of getting him well. In the columns of the Ohio Farmer I observed your advertisement and, as it was the last chance, I purchased a box at the druggists and used it as directed and before the box was used up the cut was entirely well. I intend to keep a supply on hand for emergency cases if I have to pay a dollar a box for it. Please accept my thanks for the good I have received from its use, and if you choose you can use my name and testimony.
W. S. CAMPBELL.
This penetrating, stimulating, soothing, absorbing, antiseptic, healing ointment heals from beneath the surface by disinfecting the parts, subduing inflammation and stimulating healthy granulations, not by drying and scabbing, and stimulates growth of hair, natural color. Makes quick, clean and healthy cure; heals stinging, burning, chronic saddle and collar galls, hopple chafes, abscesses, caked bag, cow pox, and hoof rot. It penetrates, stimulates, sooths and heals while horse works. Money refunded if it fails.
Price, 2-oz. box 25c; 8-oz. box 50c; 5-lb. pkg. $4.00, at all druggists and dealers or sent prepaid.

Give Postoffice and Express office with your order. Address

of animal sick, and will ship you sufficient to cure your cow with full
DR. EATON J. GROSS,
152 Congress St., Troy, N. Y

Cost of Milk in New Jersey.

Beginning April 1st, 1896, records have been kept at the New Jersey Experiment Station showing the cost of making milk. No other station has made investigations at all comparing with these New Jersey investigations in length of time, in fullness of detail, and in accurate computation of all the elements of cost, and we present a summation of the record, which will serve producers as a basis for computing their own cost of production. The New Jersey conditions and computations will answer for all the New England States and the Middle States, and therefore the appended summation is equally interesting and valuable. The station report gives the elements of cost as follows in

TABLE IV.

The kind, the amount and cost of foods for the 30 cows of the dairy herd for one year, April 1st, 1900, to April 1st, 1901:

	Pounds fed.	*Cost a ton.*	*Total.*
Wheat bran	34,000	$18.00	$288.00
Dried brewers grains	26,100	14 50	189.23
Corn meal	15,000	21.00	157.50
Linseed meal	1,800	28.00	25.20
Cottonseed meal	9,000	27.00	121.50
Pea meal	2,000	18.00	18.00
Cost of feeds			$799.43
Soiling crops	360,000	1.20	216.00
Silage	200,000	2.50	250.00
Dry cornstaks	20,000	4.00	40.00
Hay	30,000	5.34	80 10
Cost of roughage			$586.10

Total cost of food	$1,385.53
Cost per cow per day	12.65 cents
Cost of feeds	$799.43
Cost per cow per day	7.30 cents
Cost of roughage	$586.10
Cost per cow per day	5.35 cents
Total yield of milk	89.851 quarts
Average per cow per day	8.26 quarts
Cost of food per quart	1 54 cents
Cost of feed per quart	.89 cents
Cost of roughage per quart	.65 cents

The cost of feeds represents what was actually paid for them. The cost of hay, corn stalks and soiling crops represents the actual cost of labor, seed and manure; the farm manure being charged at the rate of $1.50 per ton.

The average cost of the daily ration was 12.65 cents, of which 7.3 cents, or 57.7 per cent, is due to purchased feeds, and 5.35 cents, or 42.3 per cent, to the cost of farm crops. The total cost of producing milk, including the cost of labor and the interest on the decrease in the value of the herd, the latter item being estimated.

TOTAL COST OF PRODUCING MILK.

Foods as per statement		$1,385.53
Labor	$600	
5 per cent int. on herd value	60	
5 per cent decrease in value	60	720.00
Total		$2,105.53
Cost of food per quart of milk	1.54	cents.
Cost of work and int. per quart	.80	"
Total cost per quart	2.34	"

TABLE V.

Average cost of producing milk for four years:

	Cows.	*Pounds.*	*Quarts.*	*Lbs. per cow.*
1896	23	1415'7	64916	6:53
1897	25	154768	7c990	6191

Milk and Cream Fat Content.

ED. HOARD'S DAIRYMAN:—I bought a De Laval Baby No. 2, hand separator and find by several tests, at several places and times, two-tenths of one per cent butter fat. Would you call it clean skimming? My average test is 4.2, and at the creamery, they allow me 27 per cent on cream. Is that right? My first test was 30, then 28, next 27. I turn it as regular as clock work. Milk is separated as it comes from cows; didn't change anything on separator; don't mix cold and warm cream together; keep the cream in a very cold place, and cannot account for the change.

When I started in, it took 7¼ pounds of milk to one pound of cream, now it takes 8½ pounds at the same test of milk 4.2. Could you tell me what cream test I ought to have on milk testing 4.2? Please answer through your paper, others are interested in it. A. F.

Don's Prairie, Cal.

We can only repeat what we have so often said in the past, that both milk and cream vary in per cent of fat without any known reason, and that by no known method can a dairyman with a hand or power separator, obtain cream containing the same amount of fat from day to day. All dairymen should buy and use a Babcock test, then they would know and not guess the amount of fat they are producing and selling.

The cow is an uncertain quantity as a fat producer; always was and always will be and until the dairyman knows for himself and does not depend on the say-so of other men, there will always be room for discussion and controversy as to the amount of fat supplied to the creamery. In the above case, fresh cows in the herd or turning the cows on new grass pasture would account for any changes in the quality of cream. Also the separator changes as well as the cow. The skim milk should not contain more than 0.1 per cent of fat. More than that is a waste. There is nothing in the above statement to indicate what your cream should test, as we do not know how much cream is taken from the milk; it may be anywhere from 20 to 40 per cent fat, But if 20 pounds of cream are taken from every 100 lbs. milk, the cream should contain 20.5 per cent of fat. allowing a loss of 0.1 per cent in the skim milk.

Difference in Farms and Pastures.

Is it a fact that cows will milk better on some farms than others, although cared for by the same parties, and with seemingly the same care? Are grasses on some farms better adapted to producing milk than others? If you can give me any light on this, it will be greatly appreciated.

Clinton, N. Y. A. W. R.

There is, of course, very great difference in farms and pastures, as well as between different acres on the same farm. The character of the soil modifies the quality and constituent elements of the herbage in a very marked degree.

The Relative Value of Alfalfa, Wheat Shorts and Skim Milk to Supplement Corn for Fattening Pigs.

(Press Bulletin.)

The object of the experiment just performed at the Nebraska Experiment Station and described below was (1) to show that corn can be fed more economically in conjunction with foods rich in protein and mineral matter, and (2) to determine which of three common foods is the cheapest source of protein.

Twenty pigs, uniform in type, all in good condition, were placed in four lots, five pigs in each lot. They were put on their experimental rations long enough to become accustomed to the change before the initial weighings were made.

The alfalfa fed in this experiment was in the nature of chaff, consisting mostly of leaves which had fallen from the hay as it was thrown from the mow to the barn floor for cattle. For the purpose of making a true comparison of these leaves with the whole plant, an analysis was made. The leaves were found to be 40 per cent richer in crude protein than the entire plant, 30 per cent higher in fat, 15 per cent higher in mineral matter, and 50 per cent lower in crude fiber, which substance is largely indigestible matter. This chaff was first mixed with the corn meal, then placed in the feed trough, where it was made into a thick slop with water. The other lots were fed in the same way, except that the feed for lot 2 was mixed with skim milk instead of water.

FINANCIAL STATEMENT.

With the alfalfa hay worth $7 per ton, the leaves, containing 40 per cent more protein, would be worth approximately $10 per ton. The shorts cost $12.50 per ton, delivered. The Dairy Department charged fifteen cents per hundred for the skim milk used. Corn was delivered to the barns at thirty cents per bushel. Adding the usual rate of six cents per hundred for grinding, the corn meal cost $12 per ton. At these prices, each hundred pounds of gain in the several lots cost as follows:

Lot 1.	Corn alone	$4.48
Lot 2.	Corn and skim milk	3.97
Lot 3.	Corn and shorts	3.53
Lot 4.	Corn and alfalfa	3.40

The skim milk pigs were the most hearty feeders and made the heaviest gains, but it proved a more expensive source of protein at the prices quoted.

This experiment shows that at the market prices quoted and in the proportions used in the experiment, skim milk will make corn bring four cents more per bushel, wheat shorts eight cents more, and alfalfa leaves nine cents more. Assuming that only 5 per cent of the 252,520,173 bushels of corn produced in Nebraska this year, is being fed to hogs as a single food, these figures would go to show that over $1,000,000 more wealth would be added to the state if wheat shorts or alfalfa were substituted for one-fifth of the corn fed.

THE SLAUGHTER TEST.

Since corn is deficient in protein and mineral matter, we should naturally expect that pigs when supplied more of these materials from other sources, would have a greater proportion of lean meat, more blood and bone, better developed vital organs, and therefore greater bodily vigor.

After the pigs were finished for market, one was selected from the alfalfa lot to represent the pigs that were supplied more protein. A pig twelve pounds heavier was taken from the corn-fed lot. These were both slaughtered and cross-sections of the carcasses placed before the students of the School of Agriculture for examination. All were quick to identify the alfalfa-fed pig by the thicker streaks of lean and thinner layers of fat meat. Both the pigs dressed 83.7 per cent of their live weight. The internal organs weighed as follows:

	Corn Pig.	Corn and alfalfa pig.
	Pounds.	Pounds.
Heart	.7	.7
Lungs	1.2	1.4
Liver	3.4	3 9
Blood	5.4	5.7
Intestinal fat	5.	5.7

This slaughter test shows that by supplying more protein, in this case by feeding alfalfa, we get a greater development of internal organs and more health and vigor. Undoubtedly, if more attention were given to supplying such foods as will bring about a healthy organism, losses from cholera and other diseases would be greatly reduced.

The strength of the thigh bones was tested by providing supports at both ends, applying pressure in the middle. This test was made in a machine for testing strength of materials. The bones of the corn-fed pig measured one-sixteenth of an inch larger in diameter. One bone from the corn-fed pig broke under a pressure of 320 pounds, and the other 330 pounds. One of the bones of the corn-and-alfalfa-fed pigs broke at 500 pounds, and the other at 520 pounds. From this test it is evident that break-downs, which often occur in heavy corn-fed hogs, are the fault of the feed rather than the animal. It further shows that the ability of the hog to stand up well on legs is a matter of density of bone rather than size.

In another experiment, varying quantities of alfalfa will be fed to determine the best proportion for making the most economical gains.

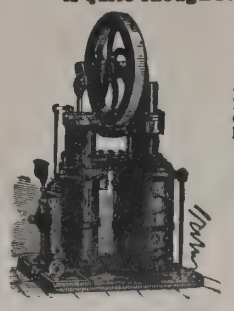
H. R. SMITH.
Nebraska Experiment Station.

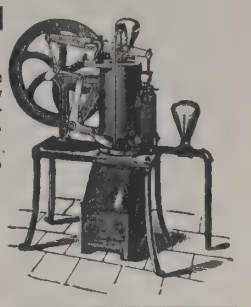
The Tennesee Farmers' Convention.



ED. HOARD'S DAIRYMAN: — The Southern farmer has come to appreciate the value of education. This was shown at the 28th annual meeting of the East Tennessee Farmers' Convention recently held in Knoxville, where over 1,200 of the best farmers from Tennessee, Kentucky, Virginia, Alabama, Georgia and the Carolinas, assembled. While a number of gentlemen of national reputation were present, they did not have a monopoly of the good things, for rarely have better discussions been heard from the farmers. This is a healthy sign; it shows that the farmers are thinking and reading and equipping themselves to meet their difficult problems.

The subject of grasses attracted a good deal of attention. Blue grass had many advocates, but as it is only adapted to certain sections; there were many who favored Bermuda. Gentlemen who have had experience with this grass asserted that it would produce 200 pounds of beef per acre. One of the best papers presented was on tall oat grass. It was shown from the results of investigations at the Experiment Station, that excellent hay and pasture can be had from combining tall-oat grass, orchard grass and meadow fescue with red or alsike clover.

There is a growing interest in stock husbandry. This was evidenced by the crowd surrounding Prof. Shaw while he scored some typical beef and dairy cat-



HALF ENOUGH WATER

Is quite enough for some people, but most people want water every day. If

RIDER or ERICSSON HOT AIR PUMPS

Are used you can have water every day in the year, and your cook or stable boy is the only engineer needed. 25,000 in daily use. Catalogue "B 5" on application to nearest store.

Chloro-Naptholeum Dip

Cures SHEEP SCABS and TICKS. CHLORO-NAPTHOLEUM DIP—the great stock remedy—cures all ailments of sheep; scabs and itch, ticks and lice; heals sores, scratches and cuts. It is strictly non-poisonous, will not injure eyes nor harm if swallowed. Veterinarians prescribe it as a drench for the *cure of Stomach Worms in Sheep.* Get our *free book* on the treatment and prevention of sheep and cattle diseases, with facts based upon Government experiments and reports from prominent breeders. It is the Sheep Breeder's Guide to Wealth. CHLORO-NAPTHOLEUM DIP not only keeps sheep healthy and free from parasites, it increases the growth of wool and makes the clip more valuable. Lime-Sulphur, nicotine and arsenical dips, and all the dangerous kinds, have long since yielded place to CHLORO-NAPTHOLEUM DIP the safe, economical and efficient dip for sheep, hogs, cattle and all stock. *PRICES, Freight Prepaid,* 1 gal. $1.50; 5 gals. $6.75; 10 gals. $12.50. Larger lots at lower rates. *Local Agents* make money by our liberal terms. Write. We sell dipping tanks and sprayers at special low prices to our customers. Prices on request. Write for Sheep Book, or book on diseases of any stock, sent free. West Disinfecting Co., Inc., 8 E. 69th St., New York.

What Prof. Shaw, Professor of Agriculture, Michigan Agricultural College, Says About Zenoleum Dip:

"Zenoleum was used quite extensively by the writer during the last year of his connection with the Montana Experiment Station. It was used most largely in the Swine Department. Among the uses to which it was put are the following: 1—Mange. We found applications of Zenoleum to give a perfect cure in case of hog mange with one or two applications. 2—In the case of a skin disease causing a scurfiness, the exact cause of which was not well understood, and which resulted in the loss of hair over almost the entire body, applications of Zenoleum completely removed the cause of the trouble. 3—In the case of an outbreak of hog cholera, the indications were that the mortality was reduced among the mature animals. Small quantities were given daily in the food fed. 4—We found it very useful in maintaining the best sanitary conditions among the pens."

Send for copies of "Zenoleum Veterinary Advisor" and "Piggie's Troubles" and see what others say about it. Books mailed free. Sample gallon of Zenoleum $1.50, express prepaid. Five gallons $6.25, freight prepaid.

"The Great Coal Tar Carbolic Dip." ZENNER DISINFECTANT CO., 34 BATES STREET, DETROIT, MICHIGAN.

tle. Many of these persons had never seen a score card or given any consideration to animal conformation, and they were delighted to learn the relative value of the specific points and the conformation indicating excellence for a particular purpose.

Prof. Massey's papers on Market Gardening and the Cow Pea were also greatly enjoyed. One of the warmest discussions was on the relative merits of red clover and cow peas.

There is a growing interest in the silo. Several gentlemen who have had years of experience prepared models and brought them to the meeting to show the best and cheapest methods of constructing silos and preserving the food. Though two hours were devoted to the subject of silos it was only well begun when adjournment became necessary. A number of the models have, therefore, been put away for the next meeting, when, if necessary, a half day will be devoted to the silage question.

Hon. W. W. Ogilvie, Commissioner of Agriculture for the state, gave an interesting address on the work of his department. It is expected that with the liberal appropriation which the last legislature made for institutes, a complete system of meetings will be organized.

The meeting closed with a visit to the Station farm, where the delegates had an opportunity of looking into the excellent work being done there. The farm was the picture of neatness, and though things had suffered from the extremely dry weather of the past six weeks, all were surprised to see everything looking so well. After refreshments had been served, the visitors wended their way homeward well pleased with what they had seen and heard and unanimously agreed that the 28th annual meeting was the greatest success in the history of the convention. Some people thought that the meeting of last year would never be eclipsed, but the attendance of over 1,200 farmers this year passed all previous records. The farmers of East Tennessee are to be congratulated on the splendid showing they made. An invitation is extended to all who are interested in agriculture to attend the next annual meeting.

ANDREW M. SOULE.

Knoxville, Tenn.

A Wisconsin Herd Record.

ED HOARD'S DAIRYMAN:—Four years ago last fall I begun to read your paper. I then got—Nov. $53, Dec. $52—15 cows. Before spring, 7 cows went to the shambles. Some were bought, some were raised and the next winter it was—Nov. $93, Dec. $94, 15 cows. The barn had a fit of the colds. An internal application of tarred paper at a cost of $3 effected a cure. Other improvements followed—a tank in the barn, an addition to the stable, a silo and a registered sire. Below is record of herd for year ending March 1st. 1903. Every mess of milk is weighed. Tests are made frequently. The cows are mostly fresh in early autumn. Several were disposed of, not being satisfactory; one heifer was kept only a month. Bran is figured at $15; clover hay at $10. I make no comments, each man draws his own moral when he reads a story.

Cows booked during year, 16--8 cows, 8 heifers.
Cows disposed of during year, 5—2 cows, 3 heifers.
Cows milked all the year, 11 cows.
Average No. for the entire year.....13.8

Cash from creamery $812
Skim milk at 20 cts. per 100.....$140
Estimated cream and milk used on table and feed to calves.....$50

Total.....$1002
Feed—hay 5, silage 2½, bran 6, bundle corn 1½.....15cts.
Total with pasture at $5 per year.....$36

Total.....$496.80

Best cow (gross).....$95
Poorest.....$30
2 cows each over 400 lbs. butter.
4 cows each over 300 lbs. butter.
1 cow less than 250 lbs. butter
Grandma, Jersey, sweet 16,280 lbs.

Test made from Jan. 2 to 8, 1903; age, 6 yrs., 7 mos.; actual weight, 835 lbs.; fed 8 qts. wheat bran, 5 qts. Buffalo gluten, 4 qts. corn and oats chop, 1 qt. oil meal and 25 lbs. corn ensilage, daily—hay *ad lib.*

Capacity of Silo for Twenty Cows.

ED. HOARD'S DAIRYMAN:—Enclosed find one dollar subscription for your paper for one year, I would not be without it. Am going to build a silo, have about twenty cows. How large a silo would I need? I intend to build a brick one. Can you tell me how many bricks I would need? Our cows are up about six months in the year. Also can you recommend some good book on silos and silage? Will write you some time in the future and let you know how much good your paper has done for me. C. A. A.

Englishtown, N. J.

Perhaps as good a rule as any that can be formulated for estimating the capacity of a silo for any given number of cows is to allow one cubic foot of space for each cow for each day, silage to be fed, where the silo is twenty or more feet in depth. On this basis, twenty cows would require four thousand cubic feet of silage for two-hundred days. A silo fourteen feet in diameter and twenty-five feet deep would have 3850 cubic feet and this would allow feeding from thirty to thirty-five pounds per day to each cow for six months.

A book which treats exhaustively on the construction of silos and other farm buildings, and on almost innumerable other farm problems, is King's Physics of Agriculture. This book and Henry's Book on Feeds and Feeding, we do not hestitate to recommend to every reader of HOARD'S DAIRYMAN. By special arrangment with the publishers, we are able to furnish these books, postage or express prepaid, at publishers prices, namely, $1.75 for Physics of Agriculture and $2.00 for Feeds and Feeding.

We shall be much gratified to receive the promised communication in regard to the progress C. A. A. may have made in dairying.

The Wooden-Hooped Silo.

Has the round silo described by Jno Gould and another correspondent — made with ⅞-in. pine only—been tested sufficiently by use to be found practical?

The wooden-hooped silo mentioned so frequently of late, has been in practical use now about four years, and so far as I know, or can learn, has given the best of satisfaction. The best endorsement is that wherever they have been erected, more are being built. If Mr. C. is not satisfied, or thinks ⅞-inch lining is not strong enough, he can remedy the matter by lining up the inside wall with 1⅜ flooring, costing a little more and securing greater strength; or get it in another way, much cheaper, by springing on more hoops between the "regulars" half way to the top. This, is quickly done after the silo is built, by springing the hoop stuff to the silo and nailing round and round. For this, two thicknesses of the hoop material would be ample. This would make the hooping consist of nine regular, four and five lap hoops, and four go-betweens of two layers each. In building the silo with wooden hoops be careful in nailing, so that the nails will not center the hoops all the time. Drive them so that they will be up and down hill, so that all the width of the hoop will have its proportion of the nails, and in putting on the outside covering observe the same precaution.

In some of the later numbers of HOARD'S DAIRYMEN there has been much reference to the wooden, built-up, hoop silo, and each and all give it unqualified endorsement. In a letter just received I am informed by the writer that last year he built a wooden-hooped silo and lined it up with 2×4 hemlock bill stuff. He had it dressed and slightly beveled, and spliced on the hoops, not getting extra long material. He put on the lining by driving the nails slightly "toeing" bringing the lumber closely together. He says the silo was a great success in every way. He found that the hemlock 2×4's cost less than the pitch pine flooring, and when he fills it this season with some of the "carboliniums" he expects to have the premium silo. While his silo holds nearly 200 tons, he found that the hoops made of ½-inch by 3-inch-wide stuff, were strong beyond any possibility of giving way, and that there was never a sign that the hoops were any other than of one unchanging length, and that the silo remained perfectly firm and rigid with no signs of slackness. Another man writes that he made the hoops for his silo of 3-inch wide elm stuff, ½-inch thick, making the hoops 3x3 inches, and using a few more. Instead of lining up with pine flooring, he first lined up inside with 6-inch wide elm boards, then put on tarred paper and put on a second layer of 1x6 inch red oak lumber, breaking joints. The silo was filled in the fall of 1900 and the silage then put in is now, March 1903, being fed without loss or waste by mould or decay—all of which is fairly good testimony in favor of the wooden hoop.—JOHN GOULD in *Ohio Farmer.*

The Profitless Cow.

Much has been said and written on the subject of scrub stock, and the scrub cow has come in for her full share of condemnation. The *Live Stock Farmer* has the following to say on the subject:

"A cow census would show that, so far as the farmer is concerned, half of the cows could be sent to the butcher without loss to their owners. The public would, of course, be the loser, for a definite amount of milk would be taken out of trade, and the remainder would be in such demand that the price would be enhanced. On the farmer's side, however, the result would mean profit. Ultimately the general public might get its milk as cheap as at first, for the poor cows would no longer produce poor cows, but the entire supply of calves would come from profitable milkers. Now, year after year, the farmer puts a certain sum of money in the way of feed into his cow and gets back the same sum. He throws in his work. Most of the men that are doing this do not know it, for they have never kept an account of what they are doing. They have no idea as to the results from milking operations. They take it for granted that the hard work they are putting in is profitable. Little by little the poor cows are being weeded out of the herds, but progress is slow. We need to use more universally the milk scales, the Babcock test and the lead pencil."

For the land's sake—use Bowker's Fertilizers. They enrich the earth and the men who till it.

PIGS ARE COMING

MAKES PIGS GAIN 3 LBS. PER DAY

BLANCHARD, IOWA.

INTERNATIONAL STOCK FOOD CO., Minneapolis, Minn.

GENTLEMEN:—This is to certify that having used "International Stock Food" for three years I cheerfully recommend it to all stockmen, and especially those who raise hogs. Last spring with a bunch of the runtiest pigs I ever had they made a gain of three pounds apiece per day.

J. S. BELL.

☞We Have Thousands of Similar Testimonials and Will Pay You $1000 Cash to Prove That They Are Not Genuine and Unsolicited.☜

We own "International Stock Food Farm," which is located 12 miles from Minneapolis and contains 650 acres. We feed "International Stock Food" every day to all our WORLD CHAMPION STALLIONS, DAN PATCH 1:59 ¼ and DIRECTUM 2:05¼; to our YOUNG STALLIONS, BROOD MARES, COLTS, WORK HORSES, CATTLE and HOGS. "INTERNATIONAL STOCK FOOD" ☞3 FEEDS FOR ONE CENT☜ is Prepared from Roots, Herbs, Seeds and Barks and Won the Highest Medal at Paris Exposition in 1900 as a High-Class vegetable, medicinal preparation to be fed to stock in small amounts as an addition to the regular feed. It is a Great Aid in Growing or Fattening stock because it increases the appetite and Aids Digestion and Assimilation so that each animal obtains more nutrition from the grain eaten. We positively guarantee that its use will make you extra money over the usual Plan of Growing and Fattening stock. "International Stock Food" can be fed in safety to Horses, Cattle, Sheep, Goats, Hogs, Colts, Calves, Lambs or Pigs. It is Absolutely Harmless even if taken into the Human system. You insist on eating medicinal ingredients with your Own food at every meal. Salt is a stomach tonic and worm medicine, Pepper is a powerful stimulating tonic, Mustard is a remedy for dyspepsia, Vinegar is a diuretic. You eat these medicinal ingredients almost with every mouthful of your food, and it is proven that these Medicines promote health and strength for people and improve their digestion. "International Stock Food" contains pure vegetable medicinal ingredients that are just as safe and as necessary an addition to the regular feed of your stock if you desire to keep them in the best possible condition. "International Stock Food" is endorsed by Every High-Class Farm Paper. It purifies the blood, stimulates and permanently strengthens the entire system so that disease is prevented or cured. "International Stock Food" is sold on a "Spot Cash Guarantee" by Fifty Thousand Dealers throughout the World. ☞Your Money will be Promptly Refunded in Any case of failure. It will make your Calves or Pigs grow Amazingly and has the largest sale in the World for keeping them healthy. ☞Beware of the many Cheap and Inferior Imitations. No Chemist can separate all the Different powdered Roots, Herbs, Barks and Seeds that we use. Any One claiming to do so Must be an Ignoramus or a Falsifier.

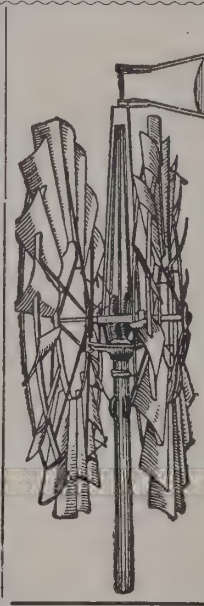
"Gwaiakowe"

Translation—Corn is king



KING CORN BINDER

In the language of the Indian, after which our great American crop was named, corn is king. The grain value of the corn crop is approximately $1,000,000,000. It is estimated that the stalks and fodder are worth as much more. Think, then, of the amount you can make by saving all of your corn crop.

The McCORMICK

corn binder and husker and shredder enables you to save this part of the corn crop that has in past years gone to waste.

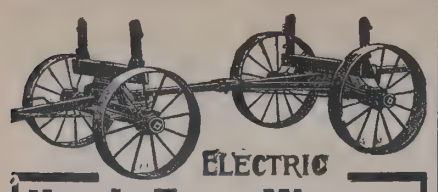
Buckets Buckets

A MULTITUDE OF BUCKETS



Buckets full of cones, buckets full of vanes, buckets full of radish graters, buckets full of blades, buckets full of discs, buckets full of contraptions that make it impossible to keep them clean. There are at least a dozen of these "bucket bowl" separators, all more or less alike and one as good as another. These cheap machines are all in the same class and not much choice.

THE TUBULAR DAIRY SEPARATOR is an entirely different type and there is but one TUBULAR. Our patents prevent other manufacturers from making the "tubular bowl", therefore they must all stick to the old style "bucket bowl" which is so unsatisfactory and which has no other recommendation than its cheapness.

Examine the **Tubular** carefully; compare it with other separators; bear in mind that it is sold on a guaranty to skim more exhaustively than other separators; to require less power to operate; to require less oil, less attention and less time to clean than any other separator. Agents in all sections of the earth where cows are kept. Write for Catalogue No. 144.

Wide Fluctuation in Milk Yield.

ED. HOARD'S DAIRYMAN:—I am a reader of your most excellent paper, I think this being the fourth year that it has been taken in our home. Although we have just now one cow only, we like to know how to treat even one cow so as to make the best of her and for her. She is a fine Jersey, but fluctuates so in her milk, (was fresh four months ago) some days falling as much as two quarts in her milk, maybe next day will give large mess. Am feeding her fresh cured alfalfa, about 14 lbs. daily, ground barley, about 8 lbs. and about 2½ lbs. cocoanut cake.

When fresh, she usually gives full four gallons of milk for several months. Just now she gives some days 12 quarts, but at others 10, and even much less. As I say, she fluctuates as I never knew her to do. Can you give me any reason?

The flies are very bad and have made lumps on her udder just where the teats join it. They matterate at times and make her very cross to milk. I use great care used in bathing and cleaning her, then using lard and sometimes sweet oil. Her udder has no fever but the flies seem to poison her just where they bite. Any suggestion would be gratefully received regarding her unsteady flow of milk, also if a change in ration is necessary.

Los Angeles, Cal. A. F. W.

It is much to be regretted that dairymen are not as solicitous to make the best of their cows and for their cows, as this correspondent is for the one cow. It is a noticeable fact that town cows, as a rule, do very much better than farm cows, and the only reason that can be assigned for this difference is that the town cow comes into much closer relation and sympathy with her care-taker than the farm cows.

A goodly number of our subscribers are like the writer of the above communication, keeping perhaps but one cow, but they seem to find it profitable to avail themselves of the information which we are able to gather and present to our readers from week to week, and they are not so apt to be governed by tradition and habit. There is abundant reason to to believe,—indeed, the truth of the proposition has been demonstrated over and over again,—that the farmer, with from eight to twenty cows, could easily increase their product from fifty to one-hundred per cent, if he would abandon prejudice, and care for his cows in a more enlightened manner and with greater regularity.

Another source of great loss to the dairymen is the fact that he is prone to treat his herd as a unit rather than as individuals. For this reason, he does not know, as the keeper of one cow does, which of his individual cows are kept at a profit and which at a loss. We have yet to hear of a single instance where the farmer has adopted the plan of weighing the milk of each cow, that he has not found some members of the herd not giving milk enough to pay for their feed—regular drones living on the bounty of their betters. It is probably true that there is not a herd of dairy cows that might not be improved by eliminating two or more cows in every ten.

But this is apart from the inquiry submitted by A. F. W. In our opinion, the plague of flies is sufficient to account for the great fluctuation in the yield of milk, as reported. We therefore advise that some measures be taken to protect this family cow from this plague of flies. Possibly, some of the preparations advertised in the DAIRYMAN might be used with complete satisfaction, but in this particular case, with only one cow to care for, it would seem to be quite possible to fasten some sort of a shield about the udder which should effectually keep off the flies. Make a canvas bag, shaped so as to fairly fit the udder and suspend this with straps, making, if necessary, some sort of a harness with a crupper attachment.

To heal the present sores, if the services of a skilled veterinarian are not available, consult the family physician, who will be able to suggest some antiseptic or emollient which will serve a good purpose.

We do not think the present system of

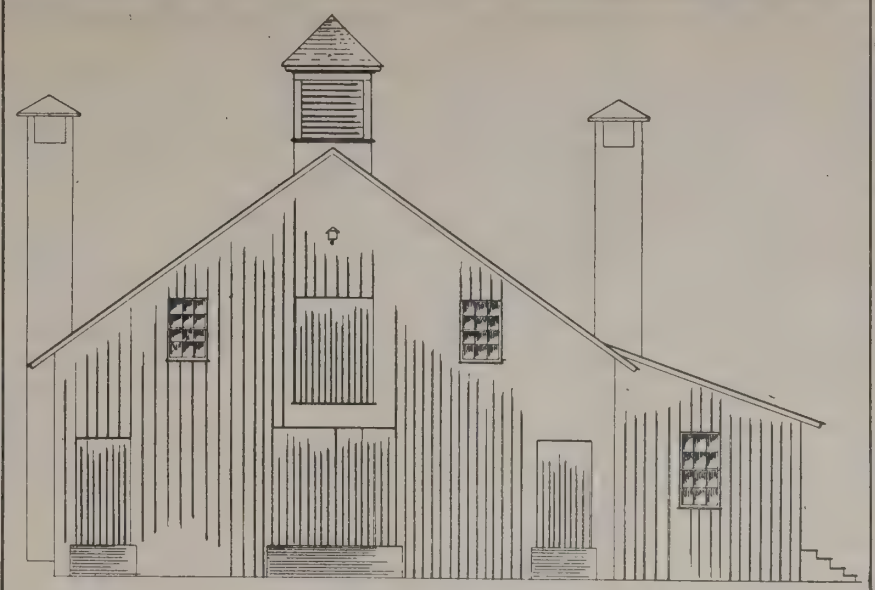
A STABLE FOR EIGHTY COWS.

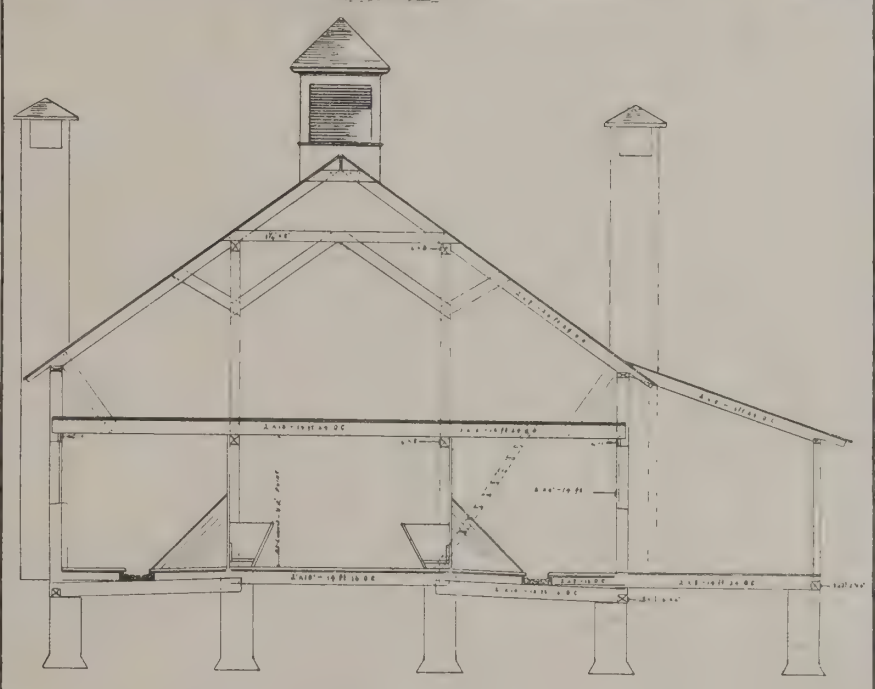


Mr. Walter E. Ward, of Albany, N. Y., has paid us the compliment of submitting for criticism plans of a cow stable prepared for him by Mr. Wm. J. Obenaus, an expert architect of that city and has kindly given permission to have cuts made therefrom for publication in the DAIRYMAN. These cuts, it is hardly necessary to explain, are zinc etchings made directly from the architects drawings, and it is somewhat unfortunate that the reduction in size has made much of the lettering indistinct.

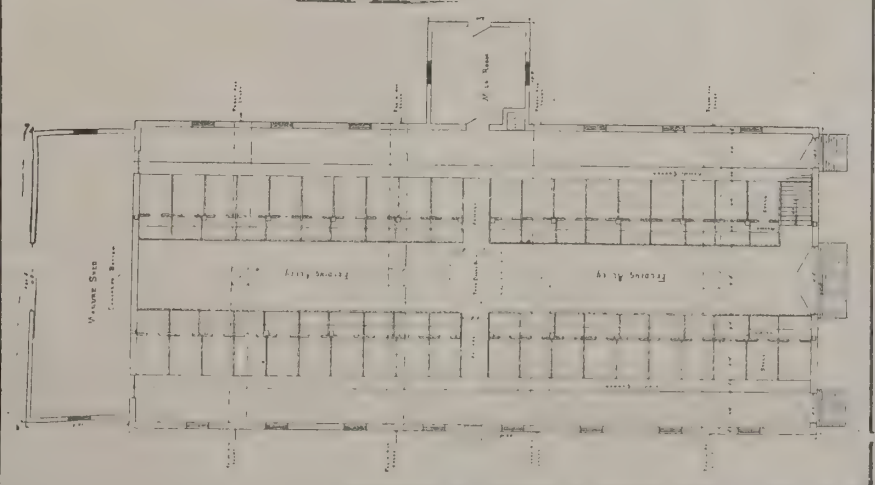
The main building is 36x80 feet in external dimensions, with an addition at one end, 12x34 feet for a manure shed, and another in the center of one side, 12x12 ft. for a milk room. Being near the barn and silos, where there is plenty of room for forage, there is no special need for utilizing the space over the stable except for grain, ground feeds and general storage. Consequently the studding for the sides is only 14 ft. It is proposed to have the floor incline toward the manure shed 12 inches in its entire length, for the purpose, evidently, of allowing the liquids to drain off. The floor is to be from 2 to 3 ft. above the surface of the ground and laid upon three rows of 2x10 joints resting on the exterior foundation walls and two central walls, 14 ft. apart from centers. The joists will be 16 inches apart on centers, and as will be seen from the cross-section, the outside rows of joists are 8 inches lower than the central row and incline very perceptibly away from the center. On top of these joists there are other 2x8 joists, presumably introduced to provide space for the concrete gutters.

Concerning these gutters and some other matters, Mr. Ward writes as follows:

"I would like especially to know your views as to whether the gutter is better concrete or plank, when it is off the ground 2 or 3 feet, resting entirely upon timbers the greater portion of the length of 80 feet. Also whether the ventilators are as good when constructed outside of the buildings with openings at the floor and top of the stable; whether they are as effective as if they were directly in the stable. The reason for putting them outside is on account of the room they would occupy inside.



"It is designed to sheathe up the outside with two thicknesses of boards, one horizontal and the outside vertical, with paper between, and ceil them up on the inside with common boards, with paper next to the studding and make both floors overhead and below double, with paper between. Also to hollow out the manure house, and have a concrete bottom."



FRONT ELEVATION

1/4 Scale

CROSS SECTION

The only other item of construction that we care to comment at length upon is that the inlets for fresh air appear to open outwardly in spaces between the upper joists, but in passing may say our judgment is that practically all the diagonal bracing in the upper story or loft, might be dispensed with. That, however, is a minor matter, of which it may be said that if they are unnecessary, they do no harm.

It goes without saying that we are glad to lay these plans before our readers and invite careful study of the same. There is very much in them to commend, especially the provision for abundant light, for excluding the cold of winter and the heat of summer by dead-air spaces in the walls, and for removing the foul air.

Upon the two specific inquiries submitted by Mr. Ward, we are of the opinion that the architect has made ample provision for supporting the concrete gutters so firmly that there is practically no danger of their cracking, and that the ventilating shafts will work quite as well on the outside of the building as on the inside. No matter where located, these shafts should be made practically air-tight from top to bottom. This can be accomplished probably most cheaply and most durably by lining them with galvanized iron. Concerning the gutters generally, we may say that the editors of this paper have never taken very kindly to the suggestion that they should be of great depth, and, as a matter of fact, the Senior in his barn has no sunken gutter. The platform upon which the cows stand is raised two inches above the general floor, and from eighteen inches to two feet in the rear of this, a common 2×4 is spiked to the floor. This space is found ample to contain all the droppings, is easily cleaned, seems to answer all the purposes of a gutter and obviates all danger of injury to the cows from stepping off and down six to eight inches. The floor is so close, and is kept so by the liquids, that it is completely water-tight, and we have little doubt as to whether it is not as cleanly as a concrete gutter would be. These and some other points which we shall mention, are, however, so much a matter of personal choice and predilection, that we think it is wise for every man to be persuaded in his own mind and satisfy that persuasion.

Personally, we prefer to have our cows face outward, and devote the central space to a driveway for cleaning out the droppings and hauling them to the fields, practically every day in the year. Of course, there may be, now and then, a day when the snow may be so drifted that it is impracticable to do this, but these are the exceptions and are liable to be of short duration. It follows, therefore, that personally, we have no use for a manure shed, but as with gutters, if others prefer to store their manure, we can have no controversy with them on such a topic. We should, however, quite seriously object to having this manure shed run entirely across the end of the stable, but would rather divide it into two sections and reserve the central part for an extension of the central drive-way, so that a team could pass in at one end of the stable and out at the other end; so that doors might be opened at both ends. This, of course, would necessitate making the two manure sheds perhaps somewhat longer in order to hold all the accumulations of the winter months. Or better still, separate the manure shed or covering entirely from the stable proper, and, with some one of the litter carriers, remove the droppings a goodly distance and thus leave both ends of the stable free for ingress or exit. If the cows are still left facing inward, the doors for entrance should be not less than four feet wide, both as a matter of safety for the cows passing through, and for greater convenience in removing the droppings.

Apart from matter upon which individual preferences may be followed without seriously impairing the usefulness or convenience of a stable, one item upon which there can be no compromise is the plan for admitting fresh air into this stable by direct openings. Constructed as this plan seems to indicate, they are no better than windows, and the objection is that when open, there is as much

opportunity for the warmer and purer air to escape as for the fresh air to enter.

The proper plan for constructing these entrances for fresh air is to have the outer opening not less than three feet lower than the inner opening. In fact, the outer opening may be carried down to nearly or quite the level of the floor. Constructed in this way, the outer air passes upward and is discharged at an opening practically on a level with the ceiling of the stable, where it mingles with the warmer air and gradually settles down to the floor and is drawn off through the ventilating shafts, but so moderately as not to develop any strong currents or drafts, and the warm air of the stable will not descend in these fresh air inlets. In this way, it is possible to keep an even and comfortable temperature in the stable at all times.

Instead of having the upper floor doubled, we should prefer to have a single floor on top of the joists and a ceiling on the lower edges of the joists in the stable, thus doing away with the corners and crevices which afford such splendid opportunities for the gathering of cobwebs, dust and litter of all kinds.

Incidentally, we may remark that in place of the timbers suggested by the architect, we would use timbers built up of 2×6 and 2×8 plank, and make provision for four or more box stalls.

The Value of Rye.

Rye is not generally considered of very great value as a hay plant. Much of this prejudice may be due, however, to the fact that it is seldom properly made. The value of hay made from any plant depends very largely upon how it was made. A Wisconsin farmer writing to HOARD'S DAIRYMAN says: "The sowing of rye for pasture, for hay, for the grain, for clover seeding and for increasing fertility has proved, in my experience, of so much profit that it is a constant source of wonder to me that farmers do not make more use of it than they do.

I always aim to have a field of rye to use for spring pasture for my cattle, as it comes on before any other pasture and just at the time when the cows are pining for something green and will surely fall off in the milk yield if they do not get it. The blue grass or clover pasture is not fit to turn into, this latitude before the first of May, (hardly then), while the rye pasture is ready by the middle of April.

Last spring I had forty acres sown in the corn field the previous fall, after the corn was in the shock, simply by drilling between the rows of shocks and harrowing once afterward at an expense per acre as follows:

Seed, 1½ bu	$.90
Drilling, 1 hour	.30
Harrowing, ⅓ hour	.10
Total	$1.30

or, $52 for the forty acres.

The use of the land is less than nothing (very much less) as the rye is sown after the corn is harvested and pastured off in time for the succeeding crop of corn, the soil working up in much better condition and richer than had the ground remained bare, besides being cleaner of weeds.

On my forty acres I pastured thirty-five head of cattle from April 11 to May 15, saving in feed, at the least calculation, $105. The cows did not require any other feed, increased in the milk flow while on the rye, and fell off immediately when taken off, although they were turned into the blue grass pasture where the feed, by the middle of May, had gotten a fine start. Will any one say that catch crop of rye did not pay me 100 per cent profit, to say nothing of the increased fertility of the land?

Many farmers have condemned rye hay simply because they thought they must wait until it was fully headed before cutting, and naturally, the resulting product was more like straw than hay, tough and unpalatable, fit for little but bedding. The time to cut rye for hay is just when it first begins to show heads; then if properly cured (and it is not hard to cure) it makes a fine hay, relished by all kinds of stock. When cut thus early there will be an almost equally large second crop of hay or pasture. I only learned to make good rye hay this past season. I did not make much, and it is long since fed out, but if I am ever confronted with the prospect of a short hay crop, I shall not hesitate to go into the rye field with mowing machine and hay loader and expect to fill my barn with good winter forage.

On my farm I have been able to raise on an average, more pounds per acre of rye than of oats, nearly as valuable for feed. I usually grind it all and feed to cows and hogs, mixed with other feed. Sometimes when the price is high, I sell it. Several years ago when the rye crop in Russia failed, I shipped a car load to Chicago, which netted me 82 cents per bushel. The yield being twenty-five bushels per acre brought me in the sum of $21, besides the straw, which is of great importance on a stock farm, where bedding is at a premium. The straw from an acre of rye is worth more than from two acres of oats, not only because there is more of it, but also because it lasts much longer, does not wet and mat down like oats or barley straw. For the last few years, however, the tempting prices offered for rye straw for the Lake Shore stables have taken much of the rye straw away from my own stock, having to content myself with the cheaper oat, barley or flax straw. I received last year $145 for the straw from twenty acres at $8.50 per ton, which was a trifle over $7 per acre for the straw alone.

Only once in twenty years have I failed of a first-class catch of clover, when sown in the early spring on the frosty surface of the rye field; the extraordinary dry season of 1901 being the exception. I have almost entirely given up attempting to seed clover in the oats, preferring the surer method of plowing the oat stubble in the fall, sowing rye and seeding in the spring.

Even when the entire crop of rye is taken from the land, it leaves the soil in the best of tilth. A few years ago we took off a crop of rye from one side of a field and a crop of oats from the other; the next year the whole field was in corn and we could see plainly where the oats and rye met, the corn on the rye ground having a stronger growth and better yield.

The growing of rye does not seem to exhaust the fertility in the soil so rapidly as most other crops. An old adage has it:

Sow wheat after wheat
You will have nothing to eat,
But rye after rye
You may sow till you die.

Most farmers need all the green feed it is possible to raise, and will hesitate to plow under a rank growth of rye, but if there is a superabundance of pasture I think it pays. J. B. Root, an old market gardener, of Rockford, Ill., says: "A crop of rye turned under, is equal to forty two-horse loads of good manure in mechanical, if not in manurial, value." Theo. Louis, the great Wisconsin hog man, has brought up his farm to a high state of fertility by plowing under successive crops of buckwheat and rye. Geo. McKerrow once said: "Some of the best pieces of corn I have seen have followed a rye crop turned under.

There is, however, one thing to be guarded against in plowing under a rye, crop, namely, that it is not left on the ground too long. A large growth of foliage removes the moisture from the ground very rapidly, and there is danger if the plowing should be followed by a dry spell, that there might not be sufficient moisture in the seed bed to germinate the new crop. If rye is kept closely pastured, there will be much less danger from this source, and the manurial effect should be almost as great.—*Prairie Farmer.*

Sunlight in Barns.

ED. HOARD'S DAIRYMAN:—Sometime ago our Station published a bulletin and gave many illustrations of model and otherwise, dairy barns in our state, and in the number shown I did not see one that had windows enough in it. The same thing occurs in the DAIRYMAN'S illustrations of cow barns. Why is it? The fellows who have covered pails with cotton, etc., are among the number who seem to think daylight and sunshine are detriments to a cow's comfort while confined in the stable. My rule for windows in a cow barn is to make out your bill for twice as many windows as you think you need, and then when your team has gone to town after them, telephone your lumber dealer to double the bill at his end.

Now, there are windows and windows. Last week's DAIRYMAN showed what was called a model dairy barn, and the windows looked more like knot holes or woodpecker holes, than windows. Get good, big double sash, 10×12 lights, 6 lights to sash, and have them not more than 8 feet apart along walls north, south, west and east. Then put in sky lights. It will pay big. Now you have windows, make all doors double, that is to open bottom and top, and never shut top door unless low temperature or storms make it necessary.

When you have light, buy a barrel of lime and have a whitewashing machine, and let your boys work it rainy days; whitewash walls and ceiling and floor if they want to. More light will be the result. A fly in our cow barn looks like a black bear on the walls that are white as—let me see—oh, yes, the cotton that is used to cover pails to keep out dirt, that can't be seen in the windowless cow barns.

Say boys, how about the Connecticut stations report on the covered pail question, is not Buff Jersey's plan upheld in it? It is all right to try to keep clean and be clean, but don't milk in a stable so dark you have to take milk outside to see if it is really clean. And about that white washing machine, ever seen one? It is a wonder. Your boys will quit ball playing any time to use it and when they have gone over your building you know every crack, crevice and corner is well covered. Ceilings can be gone over as easily as walls Last week my 11 year-old daughter and I went all over our brooder house, 12x60 ceiling and walls, in 15 minutes.

After you have given the cow barn its Sunday dress, fill machine with water, add 4 oz. of sulphuric acid to three gallons of the water and thoroughly saturate your hen houses and surrounding. Lice mites and every creeping thing will pass away. This is the best lice and mite killer in the world. Now stock men, get your herd of steers or mixed stock in a small yard fill machine with Shoo Fly and spray the cattle. Do this once a week and note results. Don't tell your dairy friends, for if you should, butter would drop to 10 cents a pound. The fly plague keeps butter up. See!

BUFF JERSEY.

Monmouth, Ill.

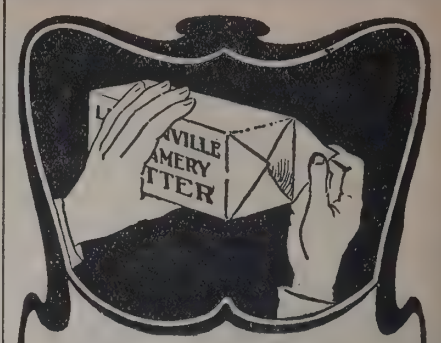
Testers and Tests.

ED. HOARD'S DAIRYMAN:—As my subscription will expire June 19th, I wish to have it continued. I have been a reader for a few years and will be a reader a few years longer, as you will find the enclosed renewal blank and money. I read the DAIRYMAN and find it O. K. in the experiments I try through it.

Now I wish to bother the editor with a few questions about the milk tester. Is there any standard tester in your state or any other state, that laws or by-laws of the state experiment stations cover? If there is please let me know. If not what make is the best and truest, as I want to get one and also a hand separator?

Next question: Does a herd of 12 to 16 cows vary in butter fat? Say their test was 4.60 per cent on a regular ration; in one month drops down to 4.15 per cent on the same feed; then raising again as butter is falling in price. At present it is 24 cts. per lb., butter fat 4.25 per cent. That looks funny. But a milk tester and a set of scales will be an eye opener to me or the creamery man. I have to cart my milk three miles, so a separator and tester and scales would be a saving of time, butter fat, price of butter and wear of team.

WM. F. L.



Delabole, Pa.

There is not to our knowledge any standard make of tester and no particular make is universally accepted as the best. On the contrary, we do not know of any make of Babcock tester which is not giving good satisfaction and none which will not be sold with a guaranty to do first-class work when, directions are followed. As a rule, we favor patronizing local dealers in purchasing all kinds of machines and machinery, but sometimes it becomes necessary, when local dealers are not disposed to get up-to-date articles, to send away. In that case, try to deal with persons or firms of recognized reliability.

It is not all unusual for the milk of a herd to show comparative wide variations from month to month, the reason for which cannot be discovered. When our friend gets his tester and his separator, he will be in a position, as every farmer should be, to protect himself in these repects.

DON'T PUT OFF

Seeing your friends and having them join in for a good club of subscribers.

Butter is Exposed

to many contaminating odors in commission houses and shops before it reaches the consumer. If the creameryman will wrap every pound print separately in

Pioneer Brand

Parchment Paper

he will shut out all foreign odors and taints and preserve its purity, sweetness and flavor. He will be safeguarding his brand in the best butter protector known. **Pioneer Parchment is a pure vegetable** parchment—not an imitation. It is tougher and stronger when wet than when dry. It imparts no taste or smell to the butter for the very good reason that it does not have either. You ought to have your name or brand printed on every package you sell. If you really make good butter, that is your most effective means of getting a reputation for it. We know how to do that printing so that it will not rub off or discolor the butter—print what you want. Our free samples of parchment paper are most convincing of their great worth to the butter maker. Write and ask for them. And our free book, **"Better Butter"** will interest and instruct you. Ask for it too.

THE PATERSON PARCHMENT PAPER COMPANY.
No. 87 8th Street, Passaic, N. J.

The Gem

FIBRE PACKAGE.

The border of this advertisement is a section of the **Package** cut in half. It shows just how the **Package** is made. Note the three thicknesses of fibre in the walls. Note how the sides and the inside bottom are pressed and dovetailed together. Note how the whole is reinforced by the extra bottom. It's lined throughout with parchment paper. Treated as it is, it **is impervious to moisture, mildew or mould.** It will not sweat in warm weather and is slow to freeze in cold weather. It's the ideal market package for anything but is specially desirable for butter. Made in numerous convenient sizes. Illustrated booklet and samples **mailed free.**

The Rape Plant, Its Culture, Use and Value.

Among all forage plants possible and profitable of cultivation in Canada none seems worthier of a more extensive use than rape. It is simple of culture; it makes a strong, rapid growth; it adapts itself quite readily to different soils and to various climatic conditions; it responds vigorously to fertilizer and to good cultivation; and, most important of all its good qualities, it is a palatable, wholesome and nutritious green food for all kinds of live stock on the average Canadian farm.

Rape stems and leaves resemble those of Swedish turnips or ruta bagas, but the roots are like those of cabbage. The leaves are numerous, smooth, more or less fleshy, irregular in outline and covered with a fine bluish bloom. The plant grows to a height of from one to four feet, according to soil and season.

The variety most commonly used in Canada is the Dwarf Essex. Several other sorts, most notably Dwarf Victoria and Broad Leaved, have been brought forward, but have not, on trial, been found to equal the Dwarf Essex in yield or in power of resistance to drought or flood.

The varieties used as forage plants are biennial, but do not, generally speaking, live through the winter in Canada, unless it be in certain parts of British Columbia. Seed, therefore, is imported and is generally good. Occasionally, however, seed of the annual variety or Bird Seed rape, is sold in the place of the Dwarf Essex or other biennial sorts, causing considerable loss to the stockman. The seedsman from whom the rape seed is secured should, therefore, be required to guarantee it as being that of Dwarf Essex.

Rape in the farm economy may be classed with root or hoed crops. It will grow on almost any kind of arable land. It does best, however, on soils rich in plant food and full of humus or vegetable matter. It should, therefore, be sown on fields prepared as they would be for roots or corn. Sod, to give a good crop of rape, must be left to rot for some time after ploughing, before sowing rape. It should be harrowed at frequent intervals and the field be in a state of perfect tilth when seeded. New land may be most profitably used to grow this crop for a year or two immediately after being cleared. Large crops of rape are practically certain on such land, and stumps or roots interfere but slightly with the harvesting.

Black soil or muck gives good returns when put under rape, and may be expected to give better returns with rape than with most other crops.

The seeding season extends from the first week in May till the end of August, subject, of course, to local climatic conditions. The crop, growing under favorable weather and soil conditions, may be fit for pasture in about five weeks. From this fact, the stockman can decide for himself how late he may venture to sow in any given district in order to ensure a sufficiently long feeding period to make it worth while. The plant will stand a quite heavy frost without suffering appreciable injury.

BROADCAST.

Rape may be sown broadcast or in rows. Where intended to be used for soiling, a thin broadcast seeding may be expected to give satisfaction. The quantity of seed required per acre when sown broadcast is about four pounds. A larger quantity of seed may be used when it is intended to cut as soon after seeding as possible; a lesser quantity where it is intended to permit the plants to attain their full growth. The leaves and small stems are the most nutritious and palatable parts of the plant, hence the above conditions of seeding.

When cutting for soiling, care should be taken to cut not lower than four or four and a half inches from the ground. By observing this precaution, a second, and even a third, crop may be expected from the same area without any further seeding.

Where sown in rows, less than four pounds per acre may be used. The quantity is, of course, affected by the space between the rows. Anywhere from 20 to 30 inch spaces give more or less satisfaction, but 22-inch spaces are probably the most profitable. Less space than 22 inches makes horse cultivation inconvenient; greater space means a slight decrease in the yield per acre. In dry soils or droughty areas, level culture should be practiced; in badly drained fields or rainy districts, it is advisable to sow on ridges.

The method of seeding in rows is, generally speaking, much to be preferred over the broadcast. The principal reasons for such preference are:—(1) Greater proportion of leaf to stem. (2) More rapid and vigorous growth. (3) Less waste when pastured, as animals naturally walk between rows, and do not, therefore, trample so many leaves or plants as when sown broadcast. (4) Permits of cultivation, which insures conservation of moisture in dry seasons, and destruction of weeds in wet times.

Rape is sometimes mixed with grain and sown in the spring. It makes a slow growth till harvest time, when after the removal of the grain it rapidly shoots up. This is a rather uncertain method and more or less objectionable when it does succeed, on account of the amount of it harvested with the grain, and so retarding the curing of the sheaves.

Clover will, generally speaking, do better than rape under such conditions.

Rape is sometimes sown in corn fields, just before the last cultivation. The results are seldom satisfactory, however, as the corn takes nearly all the available moisture and sunlight.

As already indicated, rape is an exceedingly valuable food. It is especially well fitted for sheep, swine, young cattle and steers. It has been fed to dairy cows with good results.

SHEEP ON RAPE.

Breeding ewes do well on it in summer, and it constitutes a capital feed for "flushing" or putting them into good condition for breeding in the fall. Lambs thrive upon it, but in their case it is possibly even more imperative than with older sheep or cattle to provide some other pasture (preferably other than clover) in addition to the rape.

PASTURE FOR PIGS.

It makes a very good pasture for brood sows. A little corn or barley fed in conjunction helps to balance the ration.

For fattening and growing pigs it can not be surpassed. They sometimes need to be trained to eat it, but once taught they consume it most freely. An acre sown on good land and handled carefully may be expected to carry from 25 to 40 pigs from June 15 to October. The exact number an acre will carry depends upon the season, the soil and the method of handling. To get the best results, the field should be divided into three or four equal parts and the pigs changed over to a fresh part each week or ten days.

SOILING PIGS.

Of course, greater returns in pounds of pork produced may be secured by cutting the rape and feeding it to pigs in pens, but more labor is required, and so, in a measure at least, the advantage is lost.

YOUNG CATTLE AND STEERS.

Calves relish a small amount of rape at a very early age and do well on it when fed judiciously. Young cattle thrive on it when it is fed in connection with natural grass pasture. Steers intended for stall feeding or late fall marketing cannot be better cared for than to be allowed the run of a good field of rape.

DAIRY COWS.

Dairy cows respond well to a rape ration, but judgment must be exercised in feeding, or evil odors may find their way into the milk pail.

In feeding rape to cattle and sheep care should be taken to prevent bloating. They should never be allowed to enter a rape field when very hungry, more especially should this precaution be observed if the rape is wet from dew, rain, or frost. Once accustomed to the feed, however, and having access to it at all times, little danger may be anticipated. Pigs are not affected in this way.

On account of its very juicy nature, it is practically impossible to cure rape, and when cured it is not so palatable nor so valuable a food as when green. It is not much used in making ensilage.

In sections where rather steady frost maintains (once the hard frosts come) rape may be cut and put in small piles to freeze. It should be taken to the stable the day before required for feed and allowed to thaw out completely before being fed. Repeated thawing and freezing spoil it for forage.

In chemicial composition and feeding value rape resembles clover. It is even richer than clover in flesh-forming constituents, and is exceedingly succulent. Analyses show its water-content to run from about 89 to about 94 per cent. The nutritive ratio or proportion of digestible protein (flesh-forming constituents) to digestible carbohydrates and fats (heat producing constituents) is about 1 to 3.37. Such a large proportion of digestible protein accounts for the great feeding value of the plant. Then, since average, growing animals require a ration of a nutritive ratio of about 1 to 5.5, it is easily seen why most animals require some other food not so rich in protein, along with rape. Timothy or a mixed grass pasture would be suitable for this purpose.

COST TO PRODUCE RAPE AT OTTAWA.

One Acre.

Ploughing in spring	$2.00
Harrowing (4 times) team, 3 hours	.75
Rolling, ¾ hour	.20
Seed, 3 lbs. at 8 cents	.24
Sowing, 3 hours at 13⅓ cents	.40
Hand wheel hoeing, once, 4 hours	.53
Cultivating, 3 times, single horse, ⅔ day at $2	1.50
Hoeing, once, 1 day	1.33
	$6.95

If the rent of land be considered and any commercial fertilizer, or barn yard manure, be applied, the cost of production would of course be increased. As already indicated, however, barnyard manure may be most profitably applied to land used for this crop.

Lambs and sheep have been fed with most excellent results. No exact record was kept of the amount consumed, however, as they were pastured.

Steers have been pastured here on rape and good results secured. A bunch of 22 steers made an average of 50 lbs. gain, live weight, in 3 weeks on an area of 2 acres. About 30 sheep had been allowed to pasture on part of this same area for 10 weeks. The sheep had had at the same time access to a limited area of natural grass pasture.

A study of the results shows that to produce 100 pounds of pork, only 269 pounds of meal were required in addition to the rape. The average amount of meal required for 100 pounds of pork is 425 pounds. The use of rape, therefore, saved 156 pounds of meal on each 100 pounds of pork produced, or about 1,210 pounds of meal saved by three-sixteenths of an acre of rape. All pig weights mentioned are live weight.

Many other lots have been fed similarly with similar results. In 1902, 60 pigs were fed on an acre and a half. In addition to the rape pasture, about 500 pounds of meal were required for each pig from weaning time to an average of 185 pounds live weight in October or November.

Weevils in Ground Feed.

A subscriber asks how to destroy and keep weevils out of ground feed. We are unable to give any advice on this point and refer it to our readers who may have had experience.

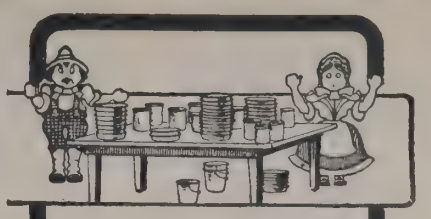
"ADVERTISEMENT."

NOT DRUGS

Food Did It.

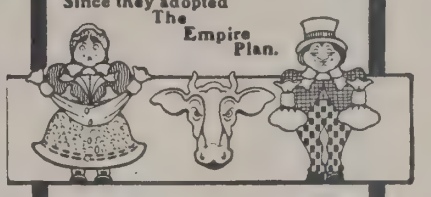
After using laxative and cathartic medicines from childhood a case of chronic and apparently incurable constipation yielded to the scientific food Grape-Nuts in a few days. "From early childhood I suffered with such terrible constipation that I had to use laxatives continuously going from one drug to another and suffering more or less all the time.

"A prominent physician whom I consulted told me the muscles of the digestive organs were partially paralyzed and could not perform their work without help of some kind, so I have tried at different times about every laxative and cathartic known but found no help that was at all permanent. I had finally become discouraged and had given my case up as hopeless when I began to use the pre-digested food Grape-Nuts.



"Although I had not expected this food to help my trouble to my great surprise Grape-Nuts digested immediately from the first and in a few days I was convinced that this was just what my system needed.

"The bowels performed their functions regularly and I am now completely and permanently cured of this awful trouble.



"Truly the power of scientific food must be unlimited." Name given by Postum Co., Battle Creek, Mich.

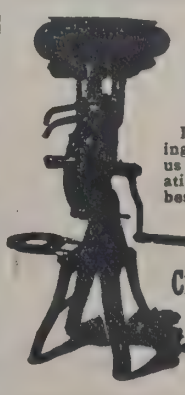
There is a reason.

Healthful desserts are just as easy as the bad kind. For further particulars see the little recipe book in each package of Grape-Nuts.

A long time ago, when they first began
To keep milch cows, poor Dairy Dan
And Milkmaid Molly had troubles galore,
And always seemed to be getting more.
They'd work and worry and stew and fret
And always would end the year in debt.
But by and by they found a way
To lessen their work and get more pay.
They bought an Empire, and every cow
Is yielding a handsome profit now.
They're Jolly Molly and Dandy Dan
Since they adopted The Empire Plan.

The Easy Way

is not always the best way, but it so happens in the case of the



Empire Cream Separator

that it is both the **easiest** and the **best.** The Empire runs more lightly than any other separator of the same capacity; it is more easily cleaned, because it has few parts; it lasts longer and costs less for repairs, because it is better built and freer from intricate mechanism. In short, it is the simplest, most efficient hand power cream separator made. We guarantee that it will do better work with less labor and trouble, than any other separator, and all we ask is a chance to let you prove our claims to your own satisfaction. What do you say?

Let us send you our good book on "Making the Dairy Pay." It's free for the asking.

Empire Cream Separator Company,
Bloomfield, New Jersey.
Western Office, Fisher Building, Chicago.

Notice to Dairymen

If you are thinking of buying a Cream Separator write us for Catalogue and information. We manufacture the best machine on the market.

Davis Cream Separator Co.,
54 to 64 N. Clinton St.
CHICAGO, ILL.

$3 a Day Sure Send us your address and we will show you how to make $3 a day absolutely sure; we furnish the work and teach you free, you work in the locality where you live. Send us your address and we will explain the business fully, remember we guarantee a clear profit of $3 for every day's work, absolutely sure. Write at once.

WILL IT PAY YOU TO TAKE HOARD'S DAIRYMAN?

W. H. Jenkins took a census in 1901 of 50 farmers who were patrons of the creamery in Montrose, Pa. Twenty-five of themread dairy papers; twenty-five did not. The twenty-five who did read dairy papers averaged $50.23 per cow for the year. The twenty-five who did not read averaged $32.95. Here is a difference of $17.28 per cow. Did it pay the twenty-five to read? Did it pay the other twenty-five not to read? That's not all. Those who did read averaged a profit over cost of food of $15.06 per cow. Those who did not read averaged a profit of 66 cents. Is not that dairy farmer standing greatly in his own ight who will not pay 2 cents a week for Hoard's Dairyman? These are hard facts worth thinking over.

We congratulate the Holstein-Friesian Association of America on the eminently sensible conclusions reached at its recent annual meeting, as announced in a circular, issued by Mr. S. Hoxie, Superintendent of Advanced Registry, under date of June 4, 1903, and published in full elsewhere in this issue.

The drouth in New England is becoming very serious. There has been no rain for 47 days, and according to reports there is absolutely no pasture, and drouth and frost have destroyed all chances of hay from meadows that are usually heavy producers. All crops are stationary, are either making no growth, or are dead from want of water.

The losses are very large at present and will be immensely increased unless conditions change very soon. The drouth extends into eastern Canada, and there has been a decided falling off in production and shipments of dairy products.

Every dairyman is, or should be, a grower of more or less fruit. More dairymen would be growers of different varieties of fruit had they not learned in the bitter school of experience that too many venders of trees and vines have not been quite reliable in their dealings. Farmers in purchasing trees, shrubs, vines and plants should endeavor to be careful to deal only with reliable parties, and it will help them in selecting such parties to read carefully the abstract of the address by our friend, Mr. J. H. Hale, of Connecticut, on the relation between the nurseryman and his customers, which is published elsewhere in this issue.

A significant illustration of the changes which have come about in recent years in the attitude of the national and state governments towards the dairy industry is furnished in the program for the coming convention of the National Association of Dairy and Food Commissioners, which is to be held at the State Capitol, St. Paul, Minn, July 21st to 24th. The program is apparently concerned more with other food stuffs than with dairy products as such, but no one who is even superficially cognizant of the work done by these various commissions can have failed to observe that much the larger part of their duty and labor is given to milk and its products and the detection and punishment of infringement upon their purity.

HOW TO TREAT A HIRED MAN.

It is not a difficult job. The golden rule will reach it. Elbert Hubbard has phrased it as follows:

"They do my work. Therefore I treat them as I would like to be treated. They are I and I am they."

When a man does your work be as patient with him as you would with yoursely if you was doing it. Use no harder language to him for his mistakes or short comings than you would to yourself when you make mistakes.

Always it is the spiteful word that breeds trouble. Actions do not make half the trouble in this world that words do. Kind, patient men make good hired men, if anybody does.

LIGHT AND VENTILATION.

These are the farmers' busy days, but they are not so busy that he should not be giving more or less thought to preparations for housing as well as feeding his cows. Stables in particular should receive very attentive consideration. Among the items not to be overlooked, are the questions of light and ventilation. Unless stables are well lighted now, windows should be put in during the summer or early fall. Unless there is proper ventilation now, arrangements should be made so that the cows can have pure air to breathe. These are not merely questions of speculative interest, but they have direct connection with practical returns. Light is a most effective germ destroyer. Fresh, pure air is absolutely indispensable for man and beast, if they are to do their best. Good air to breathe will lessen the amount of feed required and increase the returns. We beseech the readers of Hoard's Dairyman to think on these things carefully. It is not necessary to go to very great expense, but it is necessary, if one wants best returns, in some way to provide light and fresh air in the stable.

A MAN OF OBSERVATION.

For years the old Short-horn outline as to a straight back has been having "free course" in the Jersey scale of points. No one among the Jersey breeders seems to have challenged this un-dairy like top line, or asked whether there was any dairy sense in such a back. Years ago, when the senior editor of the Dairyman put forth his "Nervous Theory" concerning the physiological make up or temperament of dairy cattle, he gave the following formula as his idea of this question of conformation:

"Temperament decides function and function establishes form," and so all study of form must be based on function and temperament, the main thing in breeding being to establish a clear and decided dairy temperament or tendency, as contra-distinguished from the beef temperament or tendency. Whenever he would turn to the Jersey scale, he would strike that old Short-horn declaration in favor of a "straight back from the horns to the setting on of the tail." He opposed this as well as several other points as being out of line with the best expression of dairy temperament.

Of late the Jersey breeders have been discussing a new score card advanced by Mr. Probert, and the *Jersey Bulletin* has been publishing the comments and criticisms of many of the breeders on the same.

These comments make mighty interesting reading. The following by Mr. W. R. Spann, of Dallas, Texas, was evidently written by a man who has used his eyes and studied the dairy form as the function of milk giving has produced it in notable cows. He says:

"I consider the Probert score card a most excellent one on the whole. The wording might be shorter and the whole simplified by consolidating some of the sections into one. I have cut level back to setting on of tail 2 counts, as I think altogether too much stress is laid on a level straight back. No experienced dairyman ever saw a body with "deep, large paunch, well hooped barrel," with a back level to setting on of tail. The two points simply can't go together. This might do to judge two-year-olds by, but an aged cow with a straight level back never carries a large, well filled paunch.

The two points taken off of the level back I would add to the neck and hips. A beefy, thieving cow shows her fault first in neck and withers, and I contend that a good breeding cow must have exceptionally wide hips. Width of hips also goes with large, deep paunch. Would also have rump long "and not sloping."

The race horse breeders study the speed conformation by what is shown in the build of the best race horse. They would not take the top line of a draft horse, or the pitch of the draft shoulder, and try to breed race horses by any such outline. The breeders of hunting dogs, or game chickens, where a special function is desired in each, study the outline that belongs to the hunting and fighting function, as seen and demonstrated in the most noted of these respective breeds.

Breeders of dairy cattle should do the same thing, and Mr. Spann is right when he says: "No experienced dairyman ever saw a body with deep, large paunch, well hooped barrel with a back level to the setting on of tail."

The cows that have given renown to the Jersey breed, or any other dairy breed, do not have such backs. But that is a dairy judgment concerning dairy cattle, even if it is not Jersey like.

WHY SHOULD WE STRIVE TO MAKE PROGRESS?

It is very evident that Hoard's Dairyman is a great disturber of those who wish to let things go on in the old slipshod way. We receive a great many letters in the course of the year which indicate this fact:

One man in Ohio writes: "What is the use of so much talk about reading and studying about this dairy work? Cows have been kept here in Ohio for a hundred years, and we have got along pretty well."

Another man in Connecticut touches us up in the same way though he does confess "that the Dairyman has opened my eyes as to what can be done and how to do it, more than anything I ever struck before."

Very often we get from some, frank expressions of thankfulness for what the Dairyman is doing, practically the same view. A farmer will write renewing his subscription and he will add a few lines to say how gratified he is that he has been brought into contact with better ideas. One man in Iowa put the case in a very expressive manner. He said:

"I think I ought to tell you something about myself and what the Dairyman has done for me. I was like my neighbors, for we are all patrons of a creamery. The creamery people did not care whether we knew any more about the business or not. Sometimes I think they had rather we would keep ignorant. Then we couldn't learn much from one another because there was not a man among us that would give ten cents to know any more. Every man was cocksure he knew all there was to know about keeping cows. There was lots of grumbling and kicking, and we couldn't see that it was because we were working in the dark. One day I got a sample copy of Hoard's Dairyman. Some things I read there convinced me that here was a paper that was talking straight at the dairy farmers. I have been reading it for 8 years. I have found it hard to understand all I read there, but when I struck a word I could not understand, my daughter Lucy, and she is a good girl if I do say it, she would say, 'Go to the dictionary, father.' I feel that I have been through a course of sprouts that has made a bigger, stronger man of me. It shows in my cows, in my pigs, and in my barns. I have never made as much money on my farm as I have since the Dairyman began coming. My two boys, one is twenty and the other is seventeen, are as interested in the paper as I am, and Lucy helps us all. I don't have very good luck in getting my neighbors to take it, but they are beginning to see that this go-it-blind way don't bring in the money, nor make a man contented with his business."

There is the answer better than we could have told it in twice the space, to the question we started out with: "Why Should we Strive to Make Progress?"

Another, a hard headed, old German in Illinois, writes us in his simple, direct way that goes to the mark like a rifle shot.

"I hope you keep on with your paper. You do good; that's enough. Never mind the foolish ones; work for the men who got sense. You can't help a man who got no sense."

So we find our answer in all places and among all kinds and races of men. Somehow we must speak the message we have been commissioned to deliver. The mission of the Dairyman is to bring this business of dairy farming up to a common-sense, intelligent standard; to get men to see that there are right principles involved that should be studied out; to rouse the mind of the farmer to the taking of an intelligent interest in his work; to get him to see that he is making but little profit, and sometimes much loss, because he does not put enough brain work into the problem. And no man, in these days, can do the right kind of thinking unless he is a reader of what other men think and do. The facts brought out in Mr. Jenkins' Investigation of Creamery Patrons, show how farmers can punish themselves because they will not read, will not study, and will not try to become intelligent dairy farmers.

When a man puts the cart before the horse, his progress is slow and painful. When he tries to make money out of cows by nursing his ignorance and refusing to do anything for his better education he is putting the cart before the horse.

How much better would he feel and act if he would stop long enough to consider that ignorance of the best thought and judgment in any other business is not considered to be an aid and help to the men who are engaged in it. We say a good deal on this phase of the question. The reason we do is the fearful amount of indifference to real intelligence that prevails among the men who handle the cows of this country. Such indifference is a terrible set-back to prosperity and progress, and if they were intelligent as they ought to be, they would see it. They feel it but don't see it.

CONCERNING DAIRY PROGRESS.

Some one has said that: "All there is to human progress is the growth of good judgment among the masses." Taken widely that is true. A few men, at the start, hunt out the truth of a thing and set it up before the people. Progress in the adoption of such truth depends on how fast the rest of mankind see and appropriate the same for their own use.

Only a few years ago and the great mass of dairy farmers in this country were in the dark as to the science of dairying. More progress has been made in the last ten years in knowledge and judgment, by the average farmer, than in 100 years before. All this has come first through the agricultural chemist, then

through the practical experimenters like Professors Henry, Jordan, Armsby, Roberts, Soule, Haecker, and a host of others. Then comes the important work of the dairy paper, like HOARD'S DAIRYMAN, and the best agricultural papers who sift and assort this useful knowledge out and make it known to all farmers who have enterprise sufficient to read and learn. But still there is a great body of farmers who keep cows, who can never learn any new and important truth or improvement until their more intelligent neighbors take it up and maybe have enjoyed its benefits for ten years or more. It has been this way with the silo and many other improvements. In one way and another there is progress, even among the most ignorant and unprogressive.

After all, example is more powerful than precept, especially among farmers. We need in every farming community the stimulating and inspiring example of a few good farmers who believe in wise, intelligent farm methods; in improved live stock; in good modern farm buildings; in the best ideas of tilling the soil, in short, who believe in the use of good brains in farming, and who believe there is good profit in doing all they can to make themselves intelligent. Go into such a community and it is astonishing how much more perfect, as well as profitable, farming is. Such farmers live the farmer's life like men of intelligence. There are hundreds of such communities in the United States and Canada. Such men are never heard sneering at "book farming." They read books and papers and know the value of them to sharpen the perceptions, and make sound their judgment. We have plenty of the other kind of communities also. There the standard is low. Books and papers are scarce. The district school house is an unsightly wart on the land scape. The cattle are scrubs; ideas about farming and farm manhood are low, and ignorance of good farming and everything else prevails. What a contrast!

MARKET PRICES.

It is now about time that the so-called official quotations sent out by boards of trade, butter and cheese boards and so forth, should be made to conform to the fact. It is quite a common practice for commission merchants in the East to publicly advertise that they will guarantee consignors from one-half a cent to one cent, and sometimes even two cents per pound for butter above the official quotations. This, of course, is only another way of saying that the official quotations are not reliable or truthful, that there is a market, not spasmodic but continuous, every week and every day in the year, for dairy products at a substantial advance above official quotations. More than this, it is a well known fact that some dairy butter outsells in all the leading markets every other kind of butter. Of course, not all dairy butter sells in this way, but special brands or makes that have found a market all their own. This dairy butter is consigned to commission merchants and they find a special market for it at advanced prices, and there is no good reason in the world why these prices should not find a place in the regular market report. No greater stimulus could be given to the dairy industry throughout the country, than to see published in the daily and weekly papers a truthful report of the actual sales of dairy products in the great markets of the country. Then, if A and B and C discovered that their make of butter or cheese did not command the highest prices, they would be very apt to institute inquiries as to the reasons. This might result, and probably would result primarily, in either forcing some middlemen out of the business or compelling them to render more accurate reports of sales. There is too much reason to believe that at the present time, commission men resort to leveling processes, grading up the low quality products and grading down the high quality products, just as buttermakers in Wisconsin have been in the habit of manipulating the Babcock test, professedly trying to make a fair average, but never forgetting the margin for themselves. The legislature of Wisconsin, at its recent session, under the advice of Dr. Babcock and others familiar with the facts, passed a very stringent law, forbidding all misreading or misreporting of Babcock tests. Why would not such a law applied to reports of sales by comission houses, be in the interest of fair dealing and good morals? Why should not the Congress in furtherance of interstate commerce, make it a misdemeanor for any one publishing a paper circulating in more than one state, to publish any other than correct reports of actual sales?

PAYS ITS DIVIDENDS IN GOLD.

Governor A. B. Cummins, of Iowa, in his inaugural address spoke a large truth when he said:

"The science of agriculture and analogous pursuits has in recent years received a marked impetus. The wonderful progress in learning which relates to the farm and the dairy is doing more, and will do more, to put money into the pockets of the farmer, the stock raiser and the dairyman than any other branch of educational training. Other forms of study may be curious and interesting but this form pays its dividends in gold."

There is something in that the individual farmer can appropriate. What is it that is giving this "marked impetus?" "Progress in learning," not in not-learning. Learning comes from study of the facts about us; study of the facts of other men's experience by reading; study everywhere in the things that shall make us intelligent in the business we have in hand.

A Good Creamery Bulletin.

Some of the things that a North Yakima Wash., Creamery says to its Patrons—To Get more Profit from their Dairies.

Mr. L. Englemann, buttermaker for the Rockwood Creamery Company, North Yakima, Wash., has compiled and sent out to the patrons of that plant the following circular, which is headed "Bulletin No. 1" indicating that more are to follow as thought expedient. It reads:

The Rockwood Creamery Company intends to issue bulletins from time to time, in order to keep it patrons posted on all branches of dairying and creamery work, and point out such ways that are most profitable and enjoyable.

We hope to get a hearty support from our patrons and we will do all we can to make these bulletins most interesting. There has never been a brighter prospect for dairying than now, and especially the farmers of this state realize more for their products than in any other state; besides we have excellent dairy and food laws.

Some patrons think all they have to do is to deliver milk to the creamery or separate the milk at home, and this ends their responsibility. This is a wrong idea. The relations between creamery and patron are so interwoven that one's welfare means the other's welfare too. For instance: A patron who has a good herd of cows, and knows how to feed and care for them, will always get a big check; the creamery can easily satisfy him, while on the other hand, a man with a poor herd of cows will always be a kicker, and this is natural. The business of a creamery would be more pleasant if all of its patrons would belong to the first named type of farmers. In other words, the creamery is interested that all its patrons have good cows and know how to feed and care for them.

The welfare of the patrons means the welfare of the creamery.

The patron expects that his returns are based on the top price of the market. The creamery expects that all cream and milk will be in such a good condition that it can be made into a first-class article of butter. Consequently, please take good care of milk and cream. Avoid bringing dirty or tainted milk or cream, and see that your cans and separators are kept clean.

CARE AND RUNNING OF HAND SEPARATORS.

1. Aim to have 38 to 42 per cent cream. First, rich cream will keep better, and second, the creamery does not want any skim milk. You need all the skim milk for your hogs, calves and chickens.

2. In winter time it is harder to separate milk than in summer time; consequently be sure that your milk is warm enough and run your separator a little faster than usual.

3. Be sure that your separator is level.

4. Keep your separator clean and look especially for the skim milk tubes.

5. Use only the very best of oil and clean occasionally all gearings with petroleum.

There is a drawback connected with the separator, viz.: Farmers lose sight of the test of their herds. While we admit that some farmers will soon find out whether their cows are paying or not, there are others, who lay the blame on the separator or to the creamery.

Don't forget that you can get a 40 per cent cream out of milk testing 3 per cent only.

Perhaps the Rockwood creamery may inaugurate a system by which they will test your cows and herds right along.

CARE OF THE HERD.

It is a wrong idea to believe that a cow testing 5 per cent is a good cow. The cow that gives the most butter fat within a year is the most profitable cow, no matter what her test is. Don't get the idea that a certain breed is the only and best breed. A good cow is a good cow, no matter to what breed she belongs. Select the breed you like best and which is best adapted to your circumstances, and cows that milk ten to eleven months during the year; also they may have only a fair average test.

Important points that a dairyman must keep in mind, are:

1. The bull is half the herd.
2. Raise the calves from your best cows.
3. Sell all your poor cows.
4. Keep your herds in a healthy condition.
5. Feed and milk regularly.
6. Feed only wholesome food and look carefully to the drinking water.
7. Poor food and dirty water give tainted milk and impair the health of the cow.
8. Keep your calves growing.
9. Don't feed warm milk one day and cold the next.
10. If you want a good dairy cow from your calf, get a good, long body with well sprung ribs on your calf.
11. The coat of an animal is a good indication of its condition.
12. Try to have your cows "come in" in fall and winter. Winter dairying pays the best; besides, you have more time to milk in winter than in summer.
13. Try to raise all the hay for your herd.
14. Make the most out of skim milk.
15. Dairying and hog raising are a very good combination.

If this bulletin should find the approval of our patrons and be a welcome guest in their homes, we shall issue more bulletins, treating on feeding, breeding, care of milk and cream, etc.

CREAMERY BUSINESS.

In conclusion we wish to say a few words regarding creamery business. It is a wrong idea to believe that the creameries in this city are making any money. The Sunnyside creamery has raised its charge for making butter. The Hazelwood creamery, at their Moscow, Idaho, plant, pay 2¼ cents less than market price and don't give any overrun. They charge in addition to that 2½ cents for hauling, or in all 4¾ cents without any overrun, against our 3½ cents plus 11 per cent overrun. The creamery in Walla Walla pays on the same basis as the Hazelwood. We may further say that all prices on material used in creameries have advanced.

The Rockwood creamery has purchased a new tester, especially made for us; the glassware used is also all tested as to its accuracy, and we pay the closest attention to testing, because everything is tested over again and we have on all our work a double check. The balance we use in weighing our cream is the best in the market. We do not guess on anything, but weigh and test carefully and keep posted on all new ideas and inventions. All the men we employ are competent, having years of experience, both in this state and other states, and they are all up-to-date creamerymen. The most trouble in testing hand separator cream is caused by not taking a fair sample of cream out of the can. For instance: You can not take a fair sample from a lumpy cream, or you must know how much cream to take out of cans, one containing thick cream, one containing thin cream and so on, in order to get a fair test.

The Rockwood creamery has made a study of all this, and all our men are fully acquainted with these facts; they know how to take a sample and test; they know how to test sour cream accurate, they run the tester till they get a clear test, not a milky or burned up test, which leaves too much to guess at. We weigh all our cream samples and don't use a pipette; for instance, a 40 per cent cream will show only 37.6 per cent fat by using a 17.6 cc. pipette, and even by using an 18 cc. pipette, you can not get 18 grams of cream in your test bottle, especially not so when cream is a little sour or fresh from the separator, and you require 18 grams to get a fair sample.

Remember, the creamery that gives you the fairest test is the creamery to patronize, not the creamery that makes you think they are paying a better price.

Soliciting your patronage, we remain, respectfully yours,

ROCKWOOD CREAMERY CO.

How to Preserve Alfalfa in Stack.

Broadcast seeding is best, generally, but if a drill is used care should be taken that the seed is not planted too deep. One and a half inches is deep enough; twenty pounds to the acre is the standard quantity. The best way to get your hay in stack is to commence on the first crop as soon as it is well budded for bloom. Cut one-half of say a twenty-acre field and put it into the stack; then, if the weather is good while you are cutting and stacking the last part of the field, the first part will have a great start for the new crop and will keep your haying of the three or four cuttings for the season well divided, and you will, as a rule, have a majority of your alfalfa hay bright and free from dust. And one shock of bright, clean alfalfa is worth more than a wagon load of musty, dusty stuff for your dairy cows for winter butter.

Stack in ricks not over twelve feet wide, keep sides of the stack straight and the same width as high as you can pitch off the wagon. In topping out shake the hay out and spread it carefully. Pound down the sides with the fork and tie the top before you leave the stacks. It will turn the rain as well as any hay with the same care in topping. You will be surprised how little the rain will penetrate. It is generally claimed it won't turn rain, and it won't if stuck on with lumps and chunks. The man with big fields and machinery will learn by his necessities how to work his crop.—L. MORSE in *Nebraska Farmer*.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

Siloing Clover.

Please let me know through the columns of your valuable paper, the best method of putting clover into a silo for summer use. I want to cut the latter part of June, clover enough to fill one silo (not cut with a cutter). Shall I let it cure a few hours or not? Any information will be thankfully received. Also please tell me if the second crop in September can be treated the same as the June crop. Medium red I raise. B. J. C.
Willink, N. Y.

Do not let the clover wilt, but get into the silo as soon as possible. Spread it evenly and tramp down as solid as possible. When filling is completed wet the surface thoroughly and cover with whatever is most convenient unless feeding commences at once. Second crop can be handled in same manner.

A Self-Sucking Heifer.

I have a young cow who is inclined to suck herself. Can you suggest a prevention or cure? Can it be done without disfiguring her?
Rockford, Ill. SUBSCRIBER.

Insert a common, jointed bull ring in the nose of this cow and hang two or three large harness rings in this bull ring.

Siberian Millet.

C. W. N., of Lyons, Nebraska, asks about the value of Siberian Millet as a feed for dairy cows, stating that excessive rains have seriously affected farm work in his section of the country.

Siberian Millet is a new name and we have great doubt whether it differs very materially from some of the well recognized older varieties. Any kind of millet makes good feed for dairy cows, provided it is harvested before the seeds are fully formed. What is needed is to have the nutrients in the forage and not in the seed. Cut and cure for hay very soon after the heads come into flower.

Silo Queries by a New Subscriber.

Is a silo made from 2×4s equal to patented article? Should staves be beveled? Should they be matched? Is hemlock as good as Georgia hard pine? How are oak and whitewood? How many hoops on a 12×24 foot silo? Should staves be dressed on both sides? I am a new subscriber.
Botzum, O. A. L. W.

It is hardly to be expected that a domestic-made silo will be equal in all respects to one made in a shop equipped especially for the manufacture of silos, but a domestic or home-made silo may be made to answer every practical purpose, and if the silo is more than ten feet in diameter, there is no necessity for either beveling or matching the staves. Good quality hemlock makes a good silo, but probably not as good as one made from Georgia hard pine. Oak lumber would be, perhaps, more durable, but oak has a way of swelling and shrinking so much that we should prefer either the pine or the hemlock. The lower hoops should be not more than two feet apart and after the third hoop is on, this space may be gradually increased in succession. We prefer to have the lumber dressed on both sides, but surfacing one side only suffices for all practical purposes.

Drying off Cows.

I have some cows that freshened about four months ago and I desire to fatten them for market. Can you tell me how to check or stop the flow of milk, also as to treatment and rations? Have corn and cotton seed meal. E. P. S.
Ashville, N. C.

I have a cow that I wish to dry up. Could you please tell me of some remedy for it? The cow just came in, but has cut her teats so badly that she is not suitable for a milk cow. (Mrs.) A. B.
Newman, Calif.

There are those who contend that simply ceasing to milk is an effective and safe way to dry off cows. We have never had quite courage enough to follow this plan, but at first, we milk only once a day instead of twice and then leave considerable milk in the udder. After two or three days, it will be found that the cow gives no more milk at the one milking than she did at each of the previous two milkings. We then milk only every third day and continue this until the amount secreted is materially lessened and so continue to increase the intervals from time to time until the cow becomes practically dry. Meantime, feed no grain, and if practicable, withhold all fresh feed, giving only dry fodder.

Unless one is abundantly supplied with pasturage or fodder that would otherwise go to waste, there is no profit whatever in attempting to fatten these cows. Better sell them at once for what they will bring.

A Stave Silo Query.

In building a stave silo do you advise setting the staves back on the foundation, if so, how much, or flush with the inside? Would it be possible to plaster on the bare clay, as many cisterns are made, so as to prevent water from soaking in from the sides and bottom. W. O. D.
Hanover, Wis.

The present writer in building a silo on his farm set the staves back from the inner face of the foundation wall about five inches, and this, for the purpose of enabling him to line it with a course of brick if future developments should seem to make such a lining desirable. This space or rim was filled in with clay slanting up to the staves, much as putty is used to fasten glass in a window. This clay served the double purpose of making a tight joint between the staves and the foundation and giving an easy slide to the silage over the projection.

We have had a great many reports from parties who have practiced plastering the walls of silos in clay grounds with great success. The soil on our own farm is not suitable for adopting this plan, so in building cisterns, we simply line up with a single layer of brick and put the cement on the brick.

To Get Water in Barn.

I have a barn which I wish to have stock water in. I have a No. 1 well 100 feet from the barn and a No. 1 spring 300 feet from the barn. The well is on a level with barn, the spring 50 ft. lower than barn. How had I better proceed to get water in in my barn? Can I pump water with an engine in the barn and the well 100 feet away, 78 ft. well, or will I have to use a wind mill? If you can give me any light on this question, it will greatly oblige me.

I get lots of valuable information from your paper.

I am milking 16 cows and feeding my skim milk to hogs. Use a Davis cream separator. I have a cross of Poland China and Berkshire, thoroughbred on both sides, which I make weigh at 5 1 5 months old, average for litter of 8, 216 pounds. Another litter of 9 at 6 months old averages 236 I feed corn and wheat meal with skim milk. Tell me how to get a better gain.

I am just a boy in age and only a yearling in dairy work. I have 240 acres of land.
Fair Grove, Mo.

If there is a fall of four to eight feet from the spring referred to in the above communication, we are of the opinion that the most satisfactory way to get water into the barn, would be to use one of the hydraulic rams advertised in this paper.

If there is no available fall from the spring, it is entirely practicable to pump water from the well with an engine located in the barn one-hundred feet away. This can be done, either by the use of a rope belt, or by running a shaft the distance, the shaft made of gas-pipe and supported at intervals. It is perhaps doubtful, however, all things considered, whether a wind-mill at the well would not only give equally as good satisfaction but be cheaper in the long run.

The weight of pigs reported should be fairly satisfactory. The only question is whether they could be fed to greater profit by increasing the proportion of meal to milk. Various experiments have shown that not more than from three to five pounds of milk should be fed with one pound of grain. This may not give the pigs as much drink as they would like, but if they have pure water in connection, to satisfy their thirst, there will be no more profitable way for using the skim milk.

Starting a Holstein Herd—Handling the Sire.

Would it be advisable in starting a herd of pure blood Holsteins, to start with half brother and sister, both by the same sire?

Is it best to keep the male tied up, or let run with the cattle? Subscriber.
Merced, Cal.

There is no objection in starting a herd as suggested, provided, the animals show no defects. Close breeding tends to intensify defects perhaps even more than it intensifies good qualities. Therefore, as a rule, unless one is an excellent judge of cattle, it would be preferable to have dam and sire not closely related. It is the better, because the safer, practice, not to allow the male to run with the other cattle, but keep him either tied or give him the range of a small paddock, and if possible, some company.

Salty (?) Milk.

We are having trouble with the cheese. I am making Swiss cheese and have had trouble from the start. The cows are in good flesh and milk well. My cheese maker and milkers say that some cows give salty milk from one teat and then from one of the other teats next time, and cows that were fresh this spring. Now you will confer a great favor by you or some of the patrons to tell us how to get rid of it, or what to feed to correct the trouble. S. H.
Berlin Center, Ohio.

It is almost incredible that trouble of the character represented should occur in different herds, and still more incredible, that it should travel from one quarter of the udder to the other quarter. We venture to hazard the opinion that the cause of the trouble is more with the milkers than with the cows. The only way to determine this for certain is to compare the milk when fresh drawn with other samples that have stood for a few hours. If the trouble is with the cow, the milk when first drawn will show the defect very perceptibly; but if the milker

THE REAL CRANK

Is Plainly Marked.

A crank is one who stays in beaten paths when common sense tells him to leave.

The real crank is one who persists in using coffee because accustomed to and yet knows it hurts him. It is this one who always pays the penalty, while the sensible person who gives up coffee and takes on Postum Food Coffee in its place enjoys all the benefits of returning health.

A well known manufacturer's agent of New York City visited the grocery department of one of the big New York stores not long ago and there he tasted a sample cup of Postum made the right way. He said afterwards: "Just through the energy of that young woman who was serving Postum there I became a convert to the food drink and gave up the drug drink coffee and got well.

"I had used coffee to excess and was gradually becoming a complete wreck, getting weaker and more nervous every day. I paid the penalty for using coffee and when I tasted the delicious Postum I was glad indeed to make the change.

"So I gave up the coffee altogether and have used Postum instead every since. My family at first called me a crank but seeing how Postum benefitted me the first month they all got in line and as a result of Postum's remarkable benefits to me we all drink it now entirely in place of coffee and we are well." Name given by Postum Co., Battle Creek, Mich.

There are many reasons why the Improved

U. S. SEPARATOR IS THE ONE TO BUY

BELOW ARE A FEW OF THEM:

THE U. S.

Costs no more than inferior machines
Gets More Cream out of the Milk
Is less expensive to operate
Increases the quantity
Improves the quality
Will wear longer
Soon pays for itself
Has its gears enclosed
Bowl has few parts to wash
Has simple self-emptying Bowl
Has many other points of superiority
More fully described in our catalogues which are free for the asking, all making

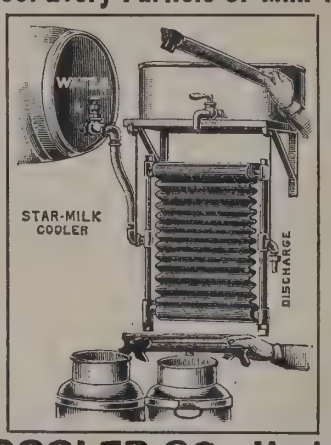
The U. S. Separator the Standard Separator of the World

For Western customers, we transfer our separators from Chicago, LaCrosse, Minneapolis, Sioux City and Omaha. Address all letters to Bellows Falls, Vt.

Vermont Farm Machine Co., Bellows Falls, Vt.

WHEN YOU SEND IN YOUR RENEWAL, SPEAK TO A FEW OF YOUR NEIGHBORS AND HAVE THEM JOIN YOU. CLUB RATES: 2 Subscriptions, $1.50; 3 Subscriptions, $2.00; 4 Subscriptions, $2.50; 5 Subscriptions, $3.00.

IT IS IMPORTANT



That You Cool Every Particle of Milk Thoroughly

Why not buy a good machine?

You purchase other machines that are first-class why not a cooler?

You will not look at a cheep Feed Cutter, Mower, etc.

If you want an easy mind, buy one of our coolers.

Stirring with a stick is not cooling.

You must have a long flow for the milk and a long flow for the water.

Thorough cooling brings good business.

Good Business means Good Money.

GOOD MONEY!!!!

STAR MILK COOLER CO., Haddonfield, N. J.

EASY. It is easy to go on losing money by taking care of milk in the old way, that is, by not taking care of it: But it is easy, too, to take proper care of your milk with a

Champion Milk Cooler-Aerator

The Champion is pre-eminently the easy Cooler—easy to buy, easy to take care of, easy to use.

A Booklet for the asking.

Champion Milk Cooler Co.,
67 Main Street, CORTLAND, N. Y.

is entirely at fault, the milk when first drawn will appear to be all right and after standing will go off in condition. In the former case, there may be something wrong with the feed or the cow, and can only be corrected by a judge of feeds or the use of some appropriate internal remedy given to the cow, but in the latter case, let the milkers thoroughly brush and dampen the udders and flanks of the cows before milking and see to it that their hands and clothing and milk utensils are thoroughly clean.

After making a thorough examination of the milk when first drawn and after standing several hours, write us again.

Selling Buttermilk at Creamery.

How should we sell buttermilk? So much for the buttermilk that you get from churning 100 pounds butter, or by the barrel, and what should we get?
Augusta, Wis. J. H. K.

Buttermilk can be sold the same as skim milk, by the hundred pounds, and it has the same value if it is kept in good condition and stored and delivered from a clean tank.

Fly Preventives.

Is there anything that money can buy, that will keep flies off cows? J. W.
Hibbing, Minn.

You will find in the advertising columns of the DAIRYMAN, a number of preperations that are successfully used for this purpose.

Calf Raising on Separator Milk.

How can I raise calves on separator milk? Would you advise cotton seed meal in it, and how prepared? How much for each calf? C. C. M.
Bar Harbor, Me.

On page 352 will be found a very full discussion of the methods of calf raising on skim milk. Cotton seed meal should not be used.

Meeting of Agricultural Educators in Pennsylvania.

ED. HOARD'S DAIRYMAN:—The State Board of Agriculture, the county chairmen of institute management, the state institute lecturers, the various agricultural organizations of Pennsylvania, with a very good representation from the State College and Experiment Station, held a three days' meeting at Huntingdon, Pa., June 2, 3, 4, that eclipsed everything of the kind previously attempted. Almost every county in the state was represented. The addresses were of a high order, delivered by such men as Dr. Geo. W. Atherton, President of State College; Prof. John Hamilton, Institute Specialist in the National Department of Agriculture, and other eminent educators.

Considerable time was used in discussing, devising and formulating plans of future action in reaching the agricultural masses with helpful educational work along agricultural lines and practically unanimous conclusions were reached that the work be continued, with conservative changes and improvements, on lines previously pursued. The Director of Institutes should feel highly gratified by the unanimous endorsement he received from almost every county in the state.

The farmers institute in our state is a most completely and systematically organized effort at agricultural education. More people are reached and more helpful practical work done than could possibly be accomplished in any other way for the same amount of money. The system is of gradual growth. Much of the pioneer work was done by the Hon. Thomas J. Edge, for many years secretary of the Board of Agriculture, nobly assisted by many capable workers, amongst them being our present secretary of agriculture, Hon. N. B. Critchfield.

The present system, however, was originated and organized by Prof. John Hamilton, now Farmers' Institute Specialist in the United States Department of Agriculture, and well might he be chosen to this newly organized division, as he undoubtedly devised one of the best institute systems we have in this country to-day. His ability along the lines of agricultural educational organization is second to none. Prof. Hamilton was succeeded by the present institute director, Hon. A. L. Martin, who has so improved and perfected the system that his over-sight and control of the work is like that of a general of an army and his responsibility is even greater. He has a corps of about 40 selected lecturers in the field most of the time during the institute season.

The state is divided into five sections of twelve to fourteen counties each. Each section is in charge of a competent, practically educated agriculturist, who makes daily reports to the director. He is accompanied by a scientific expert, generally selected from the Experiment Station. While the third man is, as Mr. Martin puts it, fresh from the farm, with his sleeves rolled up, who knows how hard a man must work and think to make mother earth yield a dollar, and who practices what he preaches. Five such trios are daily engaged for about three months in the five sections of the state, teaching some of the principles that underlie modern scientific agriculture.

In each county is a local chairman, who has charge of all local arrangements and who also makes a full report of every institute held. Thus it will be seen that the director of institutes has the entire work as it progresses, mapped out before him almost daily. But Mr. Martin does not depend on the written reports only, but one time he is in the northeastern part of the state then in the southwestern, then in the central giving his helpful advice and kindly presence; then home again to find possibly someone disabled whose place must be filled at once. I doubt if there is a busier man in the state than Mr. Martin during the institute season, but he is one of those men who never tire of well doing.

During this last year over 150,000 people attended these institutes. The agricultural outlook of the Keystone state is indeed bright when about 70% of the farmers attend these practical educational meetings.

East Berlin, Adams Co., Pa.

The Best Time to Cut Alfalfa.

Prof. Wm. P. Headden, chemist of the Colorado Agricultural College, has issued a pamphlet entitled "The Best Time to Cut Alfalfa." He says that there is a very generally accepted notion that there is a considerable difference in the value of the respective cuttings of alfalfa for feeding purposes, the third receiving the preference for milch cows, especially if it is made without the plants having been touched by frost; the first and third for sheep feeding, and so on. There are two means of investigating the subject; first by the study of the chemical composition of the plant and second by feeding experiments. So far as the composition is concerned the best time to cut alfalfa would be at that period when it would produce the greatest number of pounds of the respective food elements, expressed in the common standards.

One of the merits of hay made from the leguminous plants is that they are rich in nitrogen, the percentage of which multiplied by 6.25 is put down as the proteids. If alfalfa is cut in the bud and enough is taken to make 100 pounds of hay, the same alfalfa if allowed to stand until in half bloom, would make 126 lbs. of hay or 145 lbs., if cut in full bloom. If allowed to stand longer it would decrease. If the question were as to when is the best time to cut alfalfa to make the most hay the answer would be when it is in full bloom. But the question is: When is the best time to cut alfalfa? That time evidently is not when it will make the most hay, nor of the best quality, but when the largest yield of digestible food ingredients may be obtained. This answer involves two factors: composition and digestibility.

One hundred pounds of early-cut hay will contain 15 lbs. of albuminoids and 1.5 lbs. of amids; the 126 pounds cut in half bloom will contain 15.8 pounds of albuminoids and 2.9 pounds of amids. The 145 pounds cut in full bloom will contain 19 pounds of albuminoids and two pounds of amids. Leaving the amids out, and reducing these figures to the basis of a pound, it is found that the relative values of the three cuttings are 116, 100, and 108. Or stated otherwise, 86.2 lbs. of alfalfa hay cut in the bud, or 92.6 pounds cut in full bloom, are equal in value to 100 pounds cut in half bloom.

It is assumed that the albuminoids in the three stages of development are equally digestible. If this be true, the largest amount of digestible proteids would be obtained by cutting in full bloom.

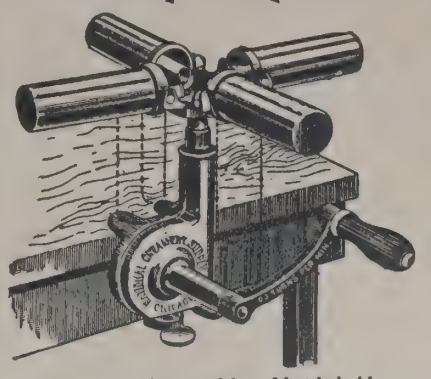
Prof. Headden concludes that after allowing for a little latitude in the use of the terms half bloom, full bloom and late bloom, the time to cut alfalfa in order to get the greatest value per acre is at the period of full bloom.—H. A. C. in *Breeders' Gazette.*

Shepherd's Aerator

Is most simple, most effective, least trouble. While you go on milking millions of air globules from the charged tank are passing up through the milk, driving out all animal heat and foreign odors. Works in shipping can. No other vessel to clean. **King among Aerators.** All dairymen prize it. Write for descriptive circular.

F. P. SHEPHERD & CO., Elgin, Ill.

Measure the Milk of each Cow



With the **Automatic Milk Scale** you can keep an accurate record of the yield of each cow, and remove the unprofitable ones from the dairy. Each button on scale arm corresponds to number of cow, and when pail of milk is weighed the button registers the weight on score card. Big money saver and money maker for farmers and dairymen. Send for testimonials and illustrated catalogue of **Bestov** dairy supplies.

Truth to Tell

There are no other milk cans made that can equal in wearing qualities the genuine

BUHL CANS

They are tinned to stay tinned, and put together to stand years of hard service. Other cans crack easily, become dented, and being lightly tinned soon rust and go to pieces. Not so with the "Buhl Factory," "Improved Elgin" and "Genuine Iowa." They will outlast any other cans on the market, and are thoroughly and quickly cleaned, **Remember,** the Buhl is the only can in the world that is made with the **Buhl "Victor" Can Breast** and the **Buhl "Victor" Round Handle.** As there are many inferior imitations of this can, we stamp all ours with the **Milk Can Trade Mark.** Look for it. Sold by all live dealers. Ask about them, or write us direct.

BUHL STAMPING COMPANY,
212 W. Larned St., Detroit, Michigan.

The Distribution of Skim Milk.....

It is known that the just complaints of creamery patrons on account of unfair distribution of skim milk are the bane of the separator creamery business. Further disputes among patrons, annoyances to managers, hindrances to the best work of buttermakers, watering the skim milk, and many other ills in the same train are unnecessary, since the

Barber-Coleman Check Pump

has for more than five years been successfully solving the problem in many different creameries. When a patron has dropped in his check he can pump the amount of skim milk called for by his check, less the percentage taken out as cream, so in like proportion to all other checks. Its measuring apparatus is just an ordinary pump which everyone understands and knows how to operate.

Allen, Secretary Food Division Kentucky Experiment Station; Hon. E. A. McDonald, State Dairy and Food Commissioner of Washington; Hon. Scott Bonham, Attorney Ohio Dairy & Food Commission.
Address—The Dairy Industry of the Country - Hon. H. R. Wright, Dairy Commissioner of Iowa
Discussion by the following: Hon. Henry E. Alvord, Chief of the Dairy Division, Department of Agriculture, Washington, D. C.; Hon. Geo. M. Whitaker, General Agent Dairy Bureau of Massachusetts; Hon. J. B. Noble, Dairy Commissioner of Connecticut; Mrs. Mary L. Wright, Dairy Commissioner of Colorado; Hon. C. P. Sherwood, Dairy & Food Commissioner of South Dakota; Hon. Frederick J. H. Kracke, Assistant Commissioner of Agriculture of New York; Hon. E. E. Kaufman, Assistant Dairy Commissioner of North Dakota; Hon. R. M. Patterson, Assistant Food Commissioner of Illinois; Hon. John M. Thomas, Secretary and Agent State Dairy Bureau of California.
Recess.

EVENING SESSION, 8 P. M.

Address—Effects of Antiseptics on the Human Body Under Recent Experiments - - Prof. H. W. Wiley, Chief of U. S. Bureau of Chemistry.
Discussion by the following gentlemen: Prof. J. H. Shepard, State Chemist of South Dakota Dr. Wm. Mitchell, State Chemist of Colorado; Prof. S. S. Ladd, State Chemist of North Dakota; Prof. Elton Fulmer, State Chemist of Washington.
Address—Food Standards - - - - Edward N. Eaton, M. S., Illinois State Analyst
Discussion by the following gentlemen: Prof. M. A. Scovell, Director of Kentucky Experiment Station, Member U. S. Food Standard Commission; Prof. B. W. Kilgore, State Chemist of North Carolina; Dr. Wm. Frear, Vice-Director Pennsylvania Experiment Station, Member U. S. Food Standard Commission.

WEDNESDAY.

MORNING SESSION, 9 A. M.

This day has been set aside for the purpose of having Manufacturers and Dealers address and take part in the Convention.
Address—Regulation of the Food Industries - Mr. R. M. Allen. Secretary of Food Division, Kentucky Experiment Station.
Address—Response, The Food Profession - Mr. L. M. Frailey, Jos. Campbell Preserve Co., Camden, N. J.
Address—The Manufacture of Flavoring Extracts Dr. V. C. Price, President Price Flavoring Extract Co., Chicago, Ill.
Discussion by the following gentlemen: Prof. R. E. Doolittle, Michigan State Analyst; Hon. Joseph E. Blackburn, Ex-Dairy and Food Commissioner of Ohio; Mr. McCormick, Of McCormick & Behnke, Manufacturers, St. Paul, Minn.; Prof. J. O. LaBach, Chemist Food Division, Kentucky Experiment Station; Mr. R. S. Fowler, of Royal Remedy & Extract Co., Dayton, Ohio; Dr. Richard Fischer, State Chemist of Wisconsin.
Address—The Manufacture and Preservation of Fruits and Vegetables - R. J. Evans Of Heinz & Co., Pittsburgh, Pa.
Discussion by the following gentlemen: Hon. A. W. Smith, Michigan Dairy & Food Commissioner, Hon. S. C. Bassett, Deputy Dairy Commissioner of Nebraska: Frank H. Madden, of Reid, Murdock & Co., Chicago, Ill.; Hon. E. O. Grosvenor, Ex-Dairy & Food Commissioner of Michigan; Mr. J. Weller, of the J. Weller Co., Cincinnati, Ohio; Mr. J. D. Miller, Attorney for Sprague, Warner & Co., Chicago, Ill.
Address—Corn Products and Their Purity - Dr. T. B. Wagner, General Superintendent Corn Products Co.
Recess.

AFTERNOON SESSION, 2 P. M.

Address—The Manufacture and Preservation of Meat Products - Prof. E. S. Manns of Armour & Co., Chicago, Ill.
Discussion by the following gentlemen: Mr. Edward Tilden, Pres't Libby, McNeill & Libby Chicago, Ill.; J. N. Hurty, M. D., Phar. D., Secretary Indiana State Board of Health and Food Commissioner: Mr. W. M. Shirley, Swift & Company, Chicago, Ill.
Address Dairy Products.
Discussion by the following gentlemen: Prof. M. A. Scovell, Director Kentucky Experiment Station; Hon. H. B. Gurler, DeKalb, Ill.; Hon. B. D. White, of St. Paul, Minn.; Prof. T. L. Haecker, Prof. of Dairy Husbandry, Minnesota Agricultural College; Mr. F. D. Coburn, Superintendent Live Stock Department, Louisiana Purchase Exposition.
Address—The Purity of Distilled Products - - Mr. R. C. Stoll, Stoll Co., Lexington, Ky
Discussion - - Hon. E. H. Taylor, Jr. Pres. E. H. Taylor, Jr., & Sons, Frankfort, Ky.

THURSDAY.

MORNING SESSION, 9 A. M.

Address—Uniform Labeling - - - Hon. A. H. Jones, Illinois Food Commissioner
Discussion by the following gentlemen: B. H. Warren, Dairy and Food Commissioner of Pennsylvania; Hon. George L. Dingman, Assistant Dairy and Food Commissioner of Minnesota; Hon. J. Q. Emery, State Dairy and Food Commissioner of Wisconsin; Hon. Horace Ankeney, State Dairy and Food Commissioner of Ohio; Hon. Moroni Heiner, Dairy and Food Commissioner of Utah.
Address—Antiseptics and Coloring in Food Products - By Prof. J. H. Shepard State Chemist of South Dakota.
Discussion by the following gentlemen: Prof. R. E. Doolittle, State Chemist of Michigan; Prof. J. O. LaBach, Chemist, Food Division Kentucky Experiment Station; Prof. Julius Hortvet, State Chemist of Minnesota; Prof. A. L. Winton, Chemist Connecticut Experiment Station; Prof. Herman Harms, State Chemist of Utah Dairy & Food Commission; Prof. J. M. Nelson, State Chemist of Nebraska Food Commission; Dr. F. Aschman, Chemist, Pennsylvanion Dairy and Food Division.

FRIDAY.

MORNING SESSION, 9 A. M.

Report of Committees.
1st Report of Regular Committees.
2nd Report of Legislative and Executive Committee.
3rd Report of Finance Committee.
4th Report of Committee on Resolutions.
Report of Special Committees.
1st Report of Committee to Confer with Association of Official Agricultural Chemists.
2nd Report of Committee on New Constitution and By-Laws.
3rd Report of Committee on National Food Law.
4th Report of Committee on Standards.
5th Report of Committee on Rulings.
6th Report of Committee on Nominations.
Election and Installation of Officers.
Adjournment.

SPECIAL NOTICE.

The foregoing will be followed as closely as possible, but other subjects will be introduced if found desirable.

The officers of the Association are especially anxious that all members of this organization be present to participate in the several sessions of the meeting, as matters of great importance are to be considered.

The convention will be held in the Senate Chamber of the State Capitol, St. Paul.

HEADQUARTERS.

For the National Association of State Dairy and Food Departments will be at the Windsor Hotel.

Headquarters of the Executive Committee will be at the Willard Hotel.

Headquarters of the Committee on Resolutions will be at the Dartmouth Hotel.

TRANSPORTATION RATES.

A rate of $16 00 for the round trip via C. & N. W. R. R. from Chicago to St. Paul has been secured. Special arrangements are made to leave Chicago on the N. W. Ltd. at 6:30 p. m., Monday, July 20th, arriving at St. Paul at 7:25 a. m., Tuesday, July 21.

Orders for tickets and sleeping car reservations can be made through Mr. H. B. Meyers, 1623 Manhattan Building, Chicago, or D. H. Hoops, General Agent C. & N. W. R. R., No. 212 Clark street. The rate for berths are $2 per berth; compartment car rates are $2.50 per berth.

During the months of July and August, summer excursion rates are in effect in almost all parts of the United States and round trip tickets can be purchased to St. Paul at about the rate of one and one-third fare for the round trip. Those purchasing tickets in this manner should try and have them read via Chicago & Northwestern, from Chicago, in order to put the entire party on the Northwestern Limited, which leaves Chicago, 6:30 p. m., Monday, July 20, 2903.

Those desiring reservations at any of the above hotels, or desiring other information, address:

HON. W. W. P. McCONNEL,
State Dairy and Food Commissioner, St. Paul, Minn.

J. W. BAILEY, Pres., Oregon.
R. M. ALLEN, Sec., Kentucky.
A. H. JONES, Illinois.
H. R. WRIGHT, Iowa.
W. W. P. McCONNEL, Minnesota.

The Cost of Milk.

Few Dairymen Know It or Try to Find Out.

What does it cost to make a quart of milk? Ask this question of almost any farmer and the answer will be: "I do not know." If all dairymen knew the true answer many of them would go out of the business at once, for one-half of the cows in the country do not give milk enough to pay for their feed at the price now received. A neighbor to whom I made this statement got mad at once, declared he had paid for a farm with milk, for twenty years selling but little else. The fact is, the cows converted the hay, grain and grass into milk, which did not sell for the market price of those products. All the profits of growing these things were swallowed by the cows, along with them, and the cows given credit for it.

The average yield of milk per cow does not exceed 3,000 pounds, and the market price of milk will not pay for the feed. There are many cows and herds which exceed this average, in every locality, and, of course, there must be as many more which give below the average. The latter class are "money losers" every time. The reason that milk sells so low is that most products sell for but little more than actual cost, and selling milk below cost, without knowing that the supply is too large. The remedy for low prices of farm products is more knowledge of their cost.

The curse of modern business is the competition of bankrupt stocks which flood the market, crowd down the price for a short time, ruin legitimate dealers and then disappear. The money to start them was earned in some other way and is lost. The operator stops until more is made in some other line. The fertility of the farm, the crops grown, supply the funds (food) for another year of trial. On the best farms, with careful management, there may be a small income, but it's the mass I wish to warn, wake up and save from toil, hard and unremitting, for mere board and clothes. The following actual figures show what it is possible to do:

A dairy of sixteen cows, many of them grade Holsteins, were well kept and fed. One can see by the figures they were far above the average dairy:

Whole number of cows milked	16
Amount of milk sold	142,226 lbs.
Average per cow	8,889 lbs.
Average price of milk per 100 lbs.	$1.041
Amount received for milk	1,481.89
Average per cow	92.61

To produce this milk it cost for:

Help hired, farm and house	$274.00
Owner	$240.00
Interest on land	$185.00
Three and a half tons hay	$35.00
Phosphates	$29.20
Threshing and silo, etc	$24.60
Paid for grinding	$34.15
Paid for feed	$438.79
Total	$1,260.74

Average cost for purchased feed per cow, $27.42. Average amount received less feed, per cow, $65.19. This leaves a profit of $221.

This is profit providing you do not reckon interest on value of cows, or depreciation in value, and allow all the food given them from the farm at the cost, instead of at the market price. The profits made on all the crops grown are included in the milk statement.

If a herd so far above the average in milk yield comes so little above the margin, where does the ordinary come in? But few dairies feed as much grain as does this man, but, aside from this, a poor cow eats about as much as a good one. It is easy to cut the 8889 pounds of milk down one-half, but you cannot cut the food bill equally.

Here is another "above the average" record, which gives but cold comfort to the careless cowkeeper:

Interest on farm and stock	$ 450 00
Depreciation and repairs	200 00
Taxes	50 00
Help and board	619 00
Twine	10 00
Fertilizer	33 80
Grass seed	23 50
Feed	323 00
	$1,708,00
Milk received	81,364 qts.
Cost per quart	.02
Money received	$1,753 23

The owner did not live on his farm but hired the help to run the farm. The loss of one cow would wipe out the profit.

How many who sell milk at the station receive an average of 2 cents per quart? These men both feed a good deal of grain and have extra good farms, which

Did You Ever Keep a Record Of Your Cows?

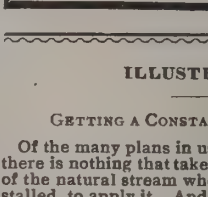
IF SO, you have felt the need of a convenient, simple and handy Record Sheet. We have had so many requests for these Record Sheets that we concluded to get up one that would "fill the long felt want." We have a very simple and complete Record Sheet for 10 cows, one month, that is printed on heavy Manilla Paper, we can send postpaid at following prices:

Price 5c Each	6 for 20c	12 for 30c	25 for 50c

SIZE 10x16 INCHES

We also have a one cow Record Sheet, heavy Manilla paper (one month) that we will mail postpaid

Single Copy 5c	5 for 15c	10 for 25c	25 for 40c



SIZE 6x15 INCHES

HOARD'S DAIRYMAN.

BINDER TWINE.
Farmers wanted as agents. AUGUST POST, Moulton, Iowa.

"NEW HERO"
excels in strength and effective working qualities and sells at a price that "fits the purse." It is the combination of these three features in the highest possible degree which a practical man looks for when buying

ENSILAGE MACHINERY.

The "New Hero" Cutters are the simplest in construction of any made; so strong that, size for size, they weigh more than any others; they have every practical advantage and improvement claimed for others and many found in no other; they are guaranteed to outlast and outwork others. Sizes, 9 in. to 26 in.; with or without self-feed table; shredder attachment if desired; swivel feed carrier. We make also a complete line of sweep and tread horse powers, shellers, huskers, feed grinders, wood saws, windmills, etc. Remember that Appleton quality is the standard of excellence, and write to-day for free catalog.

APPLETON MFG. CO.,
35 Fargo Street, Batavia, Ill., U. S. A.

ILLUSTRATION

GETTING A CONSTANT WATER SUPPLY.

Of the many plans in use for the raising of water there is nothing that takes precedence of the power of the natural stream when proper machinery is installed to apply it. And just here it is proper to remark that our advertising columns are showing in the Rife Hydraulic Engine a machine most excellently adapted to this purpose. Its varying sizes meet the requirements of a large or limited service, and the power required is so small in proportion to the duty it performs that there are but few country places with running streams where it will not give most satisfactory service. An idea of the machine may be gathered from the cut shown here. It is not only effective, but simple in the extreme and very durable. A beauty about all such powers, and particularly the Rife Engine, is

that when once installed there is practically no expense for many years to come, in the running. Many Rife Engines have been in constant operation for upwards of ten years without a dollar's worth of repairs. In the vicinity of New York, where they are best known, they are a familiar sight, seeming to have been adopted with one accord as the improved plan of raising water for all purposes at the country seats. About a dozen years ago one of these engines was installed on the famous Biltmore estate at Asheville, N. C., and it proved so effectual that to-day there are now fourteen Rifes employed, furnishing water for all the various purposes for which they have use. Very recently an irrigating plant has been established in the Hawaiian Islands, near Honolulu, with a Rife Engine for its base and furnishing 3 000 gallons per minute. These are but suggestions of its popularity and scope of duty. To the small country user it suggests easy possibilities in the way of an economical and constant fresh water supply. Whoever is wrestling with a water problem should write to the Rife Engine Co., 126 Liberty Street, New York, for their catalog and get further informotion at first hand.

produce heavy crops of grass and grain. This enables them to crowd a cow to her fullest extent without buying. They are both good judges of cows and do not keep a poor cow long. They buy and sell, not raising young stock, and often selling one nearly dry and replacing with a fresh milker.

"Would I advise abandoning the dairy?" I asked a professor of animal industry at one of our experiment stations if he would like to try to produce milk for sale at 2 cents per quart and depend on it for a living. The look he gave me and the shake of the head were answer enough. He has figures and results, from a good herd, for many years' work and knows.

No, I would not advise abandoning the dairy, but would advise knowing what it costs to keep in the business and would then, if too expensive, either change my methods or business. Knowledge lets in a good deal of light and shows things never dreamed of sometimes.

If you weigh the milk from each cow for a year, probably one or two will "go" without delay. If you have a cow get into the green oats the weight of her milk for a day or two may make you open your eyes to the possibilities of a good cow in good feed, and you may reduce the number of cows kept to that point that you can feed them well or you may grow a soiling crop another year.

If the cow with the big udder and large flow in May "peters out" in September, her milk record will remind you that appearances are deceitful and you will look for something else besides a beefy udder when you buy another.

The trouble with dairying is more in the manager than in the manger—it is "a" difference.—*Ohio Farmer.*

Seeding for Permanent Pasture.

Have 2 fields, high ground, dry gravelly soil, well drained but windy, containing 21 acres, plowed and harrowed early, but not planted; waiting 46 days for decent rain. What would you suggest, seeding at this late date, or waiting till August or September? It is my intention to make permanent pastures of aforesaid fields Am a regular subscriber at my New York City address, but green at farm operations. Hence this query.
Gladstone, N. J. G. R. M.

We would not attempt to grow a crop the present season, but seed with grasses exclusively, as soon as the summer drouth is permanently broken. Use a variety of grass seeds and do not stint in quantity.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN: — Butter dropped to 21c on the Board of Trade today. The output for the week was 829,000 pounds and sales were as follows:

Barrington, 35 tubs, 21c, to Sherwin.
Howard, 25 tubs, 21c, to Sherwin.

New York market reported firm at 21½c; receipts 240,750 tubs.

Former prices were:

	Tubs sold.	*Price.*

DAIRY MARKETS.

ELGIN, Ill., June 15.—Butter — Declined 1c a pound on the Board of Trade today owing to large receipts and excellent pasture, selling at 21c. The sales of the district for the week were 829,000 pounds.

CHICAGO, Ill., June 15—Butter—Easy; creameries, 16@21½c; dairies, 15½@18½c.

Eggs—Steady; at mark, cases included, 13¾@14¼c.

Cheese—New steady; Twins, 10½c; Daisies, 11c; Young Americas, 11@11½c.

Cattle—Prime beeves, 1,200 to 1,500 pounds, 5.25@5.40; choice to extra steers, 4.80@5.25; fair to good export and shipping steers, 4.50@4.75; medium beef steers, 4.30@4.40; plain beef steers 4.10@4.25; common to rough, 1,000 to 1,200 lbs. 3.60@4.00; good to choice feeders, 3.85@4.75; good to choice fat heifers, 4.10@5.00; poor to plain stockers and feeders, 2.85@4.00; fair to good cows and heifers, 3.20@4.00; good cutting to fair beef cows, 2.45@3.10; common to good canning cows 1.40@2.30; bulls, poor to choice, 3.20@4.30; veal calves, good to fancy, 6.00@7.00; calves, common to fair, 3.50@5.50; corn-fed western steers, 3.85@5.30; Texas bulls and grass steers, 2.75@3.30; Texas steers, fair to common, 3.85@4.65.

Hogs-Good to prime heavy shipping 6.10@6.25; good to choice heavy packing 6.00@6.15; plain to choice heavy mixed 6.00@6.10; selected butcher weights 6.10@6.20; assorted light, 150 to 195 lbs. 5.95@6.10; common to good light mixed, 5.95@6.10; thin to choice, 50 to 130 lbs., lots 5.65@6.00; stags and rough lots, 3.75@5.80.

MILWAUKEE, Wis., June 15—Butter—Creamery—extras, 22c; firsts, 19@20c; seconds, 17c; process (renovated) 18@19c; Dairy, fancy, 17c; lines, fresh, 14@15c; packing, 13c; whey, 10c; grease, 5@6c.

Cheese—American, new, full cream—Twins, 10½@11c; Young Americas, 11@11¼c: Daisies, 11@11¼c; Longhorns, 11¼@12c; low grades, 9@10c. Brick, fancy, new, 10@10½c; low grades, 9@10c. Limburger—Fancy, old, 10½@11c; low grades, 8@9c; new, fancy, 9@10c; off grades, 7@8c Swiss, drum, old, choice, 15½@16c; drum, No. 2, 13@14c; Block, choice, 14@14½c; block, No. 2, 12@13c.

Eggs—Strictly fresh laid, cases returned, 14c; dirties, 12c; seconds, 12c., checks, 10c.

FOND DU LAC, Wis., June 15—Cheese—Sales at Dairy Board today: 44 Twins at 10c, 95 at 10½c, 40 at 10¼c, and 317 Daisies at 11c. Market active.

MUSCODA, Wis,, June 15—Cheese—Offerings on Muscoda Dairy Board of Trade were: 508 boxes Twin cheese; 348 boxes sold at 10½c; 160, 10 3-16c. Market active. There will be a number of factories change from making print cheese to Twins this week.

BRILLION, Wis., June 11—Cheese—Sales on Brillion Call Board: 367 Twins, 10⅜c; 996 Daisies, 10¾c; 31 Cheddars, 11½c; 50 Young Americas, 10¾c; 28 Young Americas, 10⅝c.

SHEBOYGAN FALLS, Wis., June 10—Cheese—Twenty-one factories offered 2,690 boxes of cheese on the Call Board today and all, except 147 withdrawn, sold as follows: 25 factories at 10¼c; 707 cases Young Americas at 10¾c; 865 Daisies at 10¾c; 71 at 10⅞c; 471 cases Longhorns at 11⅛c; 403 at 11c. Market active and firm.

SHEBOYGAN, Wis., June 10—Cheese—Much activity was again shown at the meeting of the Call Board here today and the offerings of 2,290 boxes of cheese were all sold as follows: 40 boxes of Twins at 10⅜c; 45 at 10¼c; 391 Daisies at 10¾c; 619 cases Young Americas 10¾c; 569 cases Longhorns 11⅛c; 86 at 10¼c.

BOSTON, Mass., June 15—Butter—Creamery, western, extra, 22@22½c; western firsts, 21½c; dairy, 16@21c; imitation creamery, 17@19c; ladle, 15@17c; box and print, 17@23c.

Cheese—Choice, 10½@11c; Wisconsin Twins, 10½@11c.

Eggs—Nearby, 22c; western selected, 15¾c; fair to good, 14@15c; Illinois, 16c; western dirties, 13@13¾c.

PHILADELPHIA, June 15.—Butter — Dull and ¼c lower; extra western creamery, 22c; nearby prints, 23c.

Eggs—Firm, good demand; fresh near by, 18c, loss off; western, 18c; southwestern, 17c.

Cheese — Quiet, unchanged; New York full creams, choice, new 11@11¼c; fair to good, new, 10½@10¾c.

ST. LOUIS, June 15.—Butter—Steady; creamery, 16@25c; dairy, 14@17c.

Eggs—Lower, 14½c loss off.

KANSAS CITY, June 15.— Eggs—steady; Missouri and Kansas, 11c doz. cases returned; new No. 2, white wood cases included, 11½c.

BALTIMORE MARKET.

BALTIMORE, June 11—Butt r—Although the receipts of creamery continue quite liberal they have not been up to expectations; the quality as a rule is running very good. There has been no accumulation of Extras and Firsts, as the speculative and the demand for consumptive purposes has been fully equal to the supply. Seconds—While the supply is not large, it is fully equal to the requirement. Badly mottled stock is very slow sale. Imitation Creamery—Choice stock is in extremely light supply and active request. Ladles and fresh, sweet, grass stock meet prompt sale, while hay stock is more or less slighted. Packing stock continues in fairly liberal receipt, but the supply is not at all excessive, as the demand is equal to the offerings of desirable stock. Blocks and Prints—Choice to fancy invoices find ready sale. There is no demand for goods impregnated with garlic. The market closes firm and presents a healthy appearance.

N. B.—Use every effort in your power to avoid mold and mildew.

Creamery Separator, extras, 23½c; firsts, 22@22½c; seconds, 20@21c. June Creamery, extras, —@—; firsts, —@—; seconds, —@— Imitation Creamery, extras, @20c; firsts, 18@19c; seconds, 15@17c, Iowa & N. W. Ladle, extras, 18c; firsts, 16@17c; seconds, 15c. Ohio & Indiana Ladle, extras, 17@18c; firsts, 15½@16c; seconds, 14@15c. Roll, Ohio, extras, — firsts.—@—; seconds, —, Roll, W. Va., extras, — firsts, —@—; seconds, —, Ohio Store packed, extras,—c; firsts, 15c; seconds, 14@14½c. West Va. Store-packed, extras, c; firsts, 15c; seconds, 14c. Creamery blocks (2-lb.) extras, 24c; firsts, 23 seconds, 21@22c; Creamery prints (½ lb) extras, 25c, firsts, @24c; seconds, 22@23c. Md. Va., & Penna. Prints, extras, 23c; firsts, 21@22c; seconds, 18@20c. Renovated Butter, extras, 19c; firsts, 17@18c; seconds, 15@16c.

Eggs—There is a continued scarcity of strictly fancy stock, and for this kind there is an active demand at 17½c. Some of the receipts are showing the effects of heat and the loss off has been quite heavy.

N. B,—Be sure to ship in crates and not in barrels or boxes.

Cheese—Receipts ample; demand moderate; market quiet but firm.

N. Y. State—Cheddars, fine, 10¾@11c; choice, 10¼@10½c; fair, 9@9½c, Flats, fine, 11@11⅞c; choice, 10½@10¾c; fair, 9½@10c; Small fine, 11⅛@11¼c; choice, 10⅛@11c: fair, 9¼@10; Ohio Flats, fine, 9¼@10c; choice, 8¾@9c; fair, 8@8¼c; O. READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

For Sale—A quantity of second hand creamery machinery and cheese-making machinery, including a twelve horse power boiler and engine for sale cheap. Address BOX 121, Albion, Mich. 19-2

Wanted—A man to work in the cheese factory as helper. Must be neat and willing to work. State wages in first letter. Address P H. KASPER R. F. D., Clintonville, Wis.

For Sale—Registered Holstein bulls out of prize winners, ready for service. Also calves. Bargains. W. M. BENNINGER, Benningers, Pa.

Guernseys Wanted—Prices wanted on a dozen head, more or less females. Must be good individuals and descendents of good families. W. M. MARCH, 1798 W. 39th St, Los Angeles, Cal. 19-2

Position Wanted—One of responsibility for the combined work and management of manufacturing butter, cheese and process butter. Years of experience. All goods warranted. Address H, care Hoard's Dairyman. 17-3

Wanted—Graduate of Dairy School, not afraid of work and capable of managing men, as assistant manager in an Hygienic Milk Bottling Establishment. State wages expected and where you have been employed. Address, with references, SCHIER'S HYGEIA DAIRY, Baltimore, Md.

Wanted—A single man for general farming. Must be a good milker. Write, stating wages wanted, addressing ELI I. CROSIAR, Utica, Ill.

Wanted—At once, a first-class dairyman, single, to take charge of a dairy where 1000 quarts are bottled daily. Man must be strong, quick, and able to run things in a clean way. WALTER CUTTING, Pittsfield, Mass.

Wanted—Man and wife to conduct 100-acre farm near Chicago. Must be experts at butter making and poultry raising and be experienced in all farm matters. Must forward good references. B. W. S., 1443 Marquette Bldg., Chicago, Ill.

For Sale—One Holstein bull calf of Signal breeding. ST. STAINSLAUS COLLEGE, Macon, Ga.

For Sale—One No. 1 Alpha De Laval Separator, one 150 gallon Potts Pasteurizer, and one O. K. Power Buttet Worker all in good condition. Address BOX 28, Buckeystown, Md. 19-2

For Sale—One 100 lb. Embree Worker; one 150 gal. Reid Box Churn; one 1000 lb. De Laval Separator; one 8 horse power engine and boiler (on wheels). Address JAMES S. BIGGS, Rocky Ridge, Md. 19-4

For Sale—A W. H. S. Sharples separator. Run about 12 mo. Perfect order; $50. WALLACE L. COLDWELL, Blue Mounds, Wis.

Do You Want—A Hay Fork Returner? Every farmer having a barn should have one. A hummer for agents. Circulars free. ROONEY RETURNER CO., Box D., Independence Iowa. 50-tf

Wanted—Single man on large dairy. Only good milkers need apply. F. W. ADAMSON, Lake Bluff, Ill. 4-tf.

Wanted—An experienced man to take charge of milk route. Must be a single man and a hustler. State wages and references. Wanted immediately. S G. TAYLOR, Mauston, Wis. 18-3

Buff Jersey's latest book on Farm Stock and Dairy Work is full of practical things for practical people. The Silo, how to build and fill; ensilage, its value; soil, crops, variety and how to grow. Swine, poultry and many other subjects ably treated. Send 25c for copy. Monmouth, Ill. 47-tf

Practical Man Wanted—To take charge of an Indiana dairy and push sales. Single man preferred. Must be an up-to-date hustler. Address "INDIANA," care Hoard's Dairyman. 17-3

Are You Color Blind?—If not, you will appreciate the natural golden colored product of the Guernseys. Pure bred bulls and grade heifers for sale. A. H. HINMAN, Allenville, Wis. 17-4

Position Wanted—Experienced butter maker wishes to change position. Have taken Dairy Course at Ames, Iowa. Good references. Address T, care Hoard's Dairyman. 15-5

A Registered Guernsey Bull 15 months old for sale. A very fine animal. Inquire of J. S. HUNTER, Pickett, Wis. 12-tf

Half Price—Three registered Jersey heifers one year old and under. First check for $100 takes them. Satisfaction guaranteed. WALTER ZIMMARMAN, Moray, Kans. 18-2

For Sale—Davis Cream Separator, 450 lbs capacity, used 2 months, good condition. J. KOHL, Reeseville, Wis. 18-2

For Sale—One No. 3 De Lavel separator in good order, used a short time only. Putting in larger machine. FOREST HOME FARM, Purcellville, Va. 18-2

Fine Dairy Farm for Sale—Near St. Paul, Minn. 210 acres good land with ample buildings of all kinds. Page fence cedar posts. Pure bred Holstein cattle and Yorkshire swine sell readily at good prices. Good markets for all dairy products. Will sell with or without stock and other personal property. Easy terms. Enforced removal to California only reason for selling. T. S. TOMPKINS, Pasadena, Cal. 15-tf

Very Low Rates to California and Return—Via the North-Western Line. First-class round-trip tickets on sale July 1 to 10, inclusive, to San Francisco and Los Angeles. Favorable limits and stop over privileges and choice of routes. The overland limited, most luxurious train in the world, leaves Chicago daily at 8 p m. Less than three days en route. Drawing room and compartment cars, observation cars, dining cars, buffett-library cars (barber and bath), electric lighted throughout. Three trains a day from Chicago to the Coast through without change. Daily and personally conducted tourist car excursions to California, Washington and Oregon. For particulars apply to ticket agents Chicago & North-Western R'y. 16-7

Mr. Wheaton's Canadian Dairy Notes.

A Definition of Fine Butter and Cheese—Methods of Manufacture—The Season in Canada—Buying Cheese—Cheese Prices

ED. HOARD'S DAIRYMAN:—Cheese and butter exporters, dairy instructors, makers and salesmen, to the number of one hundred, met at Montreal early in June to decide upon cheese and butter standards. The readers of the DAIRYMAN will be interested in knowing what was done.

Mr. J. A. Ruddick, Chief of the Dairy Division, Ottawa, presided. A full discussion took place upon the matters brought before the meeting. Those present were seemingly unaminous in favor of adopting standards of excellence for both cheese and butter.

The following is the definition of the finest butter adopted:

"Butter—Finest Creamery butter shall be butter made in a creamery under the system known as the centrifugal or separator process.

Flavor—Sweet, clean and fresh.

Body—Good and uniform and not loose made or watery; must contain less than 16 per cent moisture to conform to the law of England. With proper care none of our Canadian butter should contain more than 13 per cent moisture.

Color—Even and uniform; should be straw colored or pale but not white or lardy.

Salt—Must not be over three per cent unless by special arrangement.

Package—Boxes must be strong, well made, of well seasoned wood, properly paraffined; of the uniform capacity of 56 lbs., clean, and in good condition for shipping. When hooks are used, four hooks on each box. Tubs must be strong, neat and of uniform size. Pure vegetable parchment paper of not less than forty pounds of paper to the ream must be used for lining the package."

The following in reference to fodder and gathered cream butter was also adopted.

"Fodder butter should be salted 4 per cent, clean in make, and clear straw color. Fresh or new made, should not be kept till stale before shipping, but should be in consumers' hands ten to fifteen days after it is made. Neat and clean 30 lb. tubs aud 56 lb. boxes only should be used, as the appearance adds much to the value of the butter.

Gathered cream butter or western Ontario—this should be shipped often and given to the consumer when fresh; three or four days make great difference to the quality.

Parchment paper should be the best: free from any inclination to mold; grading of butter is not desirable; what is No. 1 today, will be No. 2 next week."

The following requirements of finest cheese were adopted:

Finest cheese—Flavor, clean and pure.

Body—Close, good and well cured.

Texture—Silky, solid and meaty.

Color—Good and uniform.

Finish—Of good shape and fairly uniform in size, neat in finish, with good rinds and clean surfaces.

Boxes—Must be strong and close fitting."

The meeting also recommended the use of at least ¼ lb. and not more than ½lb. to each 100 lbs. of butter, of the best preservative, specially prepared for butter, and that this should be thoroughly mixed with the butter.

The most striking thing in these recommendations is, that the particular process by which finest butter shall be made, should be defined, which is tantamount to saying that good butter can be made only by this process. The cream-gathered buttermakers, of whom there is a large number in Western Ontario, will probably resent such discrimination.

Both good and bad butters have been made in the past by both the separator and the cream gathering process. It is not the latter system which is at fault, but the way in which it is managed in some sections. Nothing will be gained by putting a ban on the system itself. Why not adopt some means whereby the methods of operating it can be improved upon?

This definition of what the finest butter shall be will shut out all the butter made in the Government creameries in the Northwest territories, besides the private creameries all through the west, which are operated on the cream gathered plan, as no other is suitable to the sparsely settled west. And these Montreal dictators would, forsooth, brand all the butter of the west and of Western Ontario as not the finest because it is made by one process and not by the other.

The definition of finest cheese is a more rational one and should meet with favor by our dairymen generally. There was a feeling, before the meeting was held, that any standards for cheese decided upon would be applicable only to the districts in Eastern Ontario and Quebec, which ship their cheese to Montreal subject to inspection. Many of the dairy boards of trade in Western Ontario took this view and did not send delegates.

Many American dairymen will, doubtless, be surprised at learning that the use of preservatives had been recommended at a gathering of Canadian dairymen. There has, however, been a feeling for some time among many interested in the development of our butter trade, that a small amount of some good preservative might profitably be used in butter made for export. This feeling has crystalized into the recommendation of the Montreal meeting.

It remains to be seen how far our butter makers will go in the use of preservatives. Had a few good preservatives been named by the meeting it would have saved buttermakers from being imposed upon and sought after by manufacturers who might claim to have a good preservative when it was not.

The season of 1903 is not likely to be as prolific of good pasturage for cows as was that of 1902. In Ontario, east of Kingston, and in Quebec the dairymen are experiencing one of the severest drouths in years. The grass in these districts is so poor that cows can hardly find picking enough to keep them alive, let alone to produce milk. Many farmers are feeding last year's hay in an effort to keep up the milk flow, which has fallen off very much, greatly lessening the cheese output in these sections.

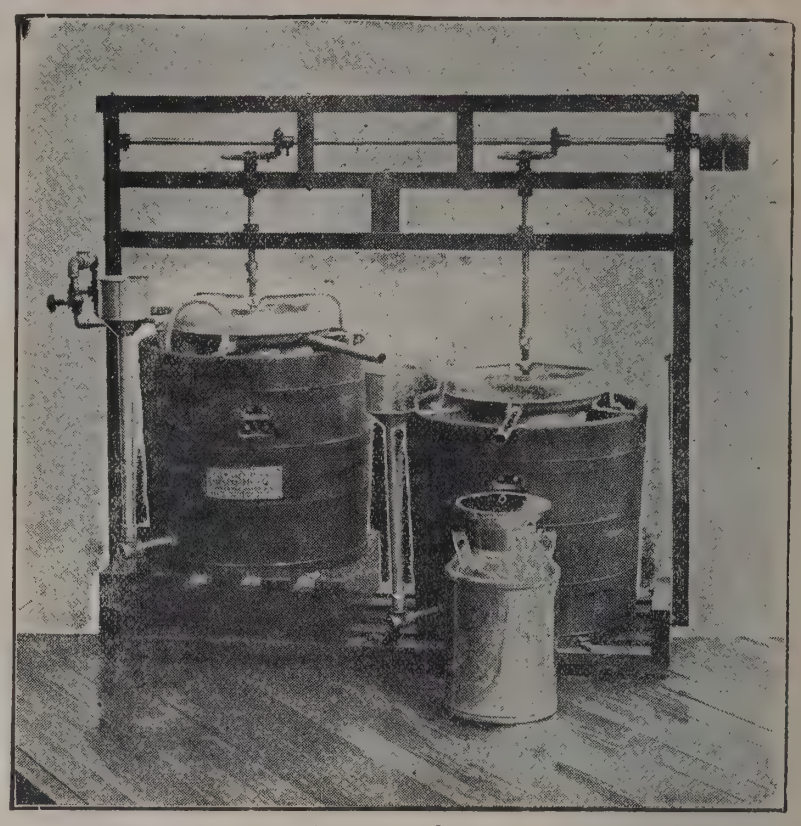
While the balance of Ontario has not suffered so much, the pasturage is not as good as a year ago, and though there has not been any serious falling off in the milk flow, it is not likely to keep up to as high a level as last year. More supplementary feed will be required, and more care in keeping the cows thrifty and in good producing trim.

Many cheese factory salesmen within the zone where Montreal inspection of cheese holds sway, strongly object to this plan as being one that gives buyers practically every thing their own way, when they get the goods under their control. The members of the Ottawa cheese board have objected very strongly to this plan. At a recent meeting it was decided to ship all cheese ready for sale into cold storage at Ottawa, the day before the market is held, and to sell after the cheese had been inspected by the buyers.

How this plan will work out, it is hard to say. A number of the factories in the vicinity of Ottawa have resolved to try it and their experience will go a long way towards influencing others similarly situated.

While the bulk of the sales made subject to Montreal inspection, turn out satisfactorily to all concerned, there is a suspicion on the part of many factorymen, that they are not always fairly dealt with. This plan certainly gives the buyer a chance to act unfairly if he so desires, and it is reported that he occasionaly does so when there is any great slump in prices. It would be fairer for all concerned if the goods could be examined before being sold.

The price of June cheese has got down near to a 10 cent basis. At the markets this week from 10c to 10½c and 10 5-16 cents are the ruling figures for the first half of June make. In Eastern Ontario and Quebec, where the effects of the drought are beginning to be severely felt, factorymen are inclined to hold back a little, expecting a higher market. But as the dry belt affects only a comparatively small area of the cheese producing area, prices may not advance on that account.



Large increases in butter supplies during the past week or two have weakened the market which stands at about 18 to 19 cents for creamery butter. The quality of the grass goods arriving is said to be excellent, which may help values.

Toronto, Canada. J. W. WHEATON.

Announcement of Nursery Inspection.

An expert entomologist, employed by the Experiment Station, will, in a few days, inspect nurseries, in accordance with the San Jose scale law. The cost of inspection, as provided by law, will be

A GREAT SUCCESS.

The Miller Cream Pasteurizer has a capacity of from 450 to 600 lbs. per hour.

Price $150 in Tin. $200 in Copper.

five dollars ($5) for each ten acres devoted wholly or in part to nursery stock grown for sale purposes. Nurserymen who have their premises inspected by the above mentioned inspector while on his regular trip will not be required to pay any part of his travetling expenses, but those who delay making application until the inspector has left the state will be charged traveling expenses in addition to the fee required by law.

All nurserymen desiring to have their premises inspected should apply at once to Agricultural Experiment Station, Madison, Wisconsin.

W. A. HENRY, Director.

Producing Clean Milk.

How Science is Applied in the Walker-Gorden Laboratory Great Establishment.

On account of the growing interest in the production of sanitary milk, the following account of the famous Walker-Gorden milk business which was recently visited by a commission of German Agriculturists visiting this country, will be interesting reading for which we are indebted to the New York *Produce Review*.

The Walker-Gordon Laboratory Company is organized to provide pure milk and cream and to furnish for infants and invalids a milk modified as to its constituents, chiefly upon the prescription of physicians. The company has laboratories in New York, Philadelphia, Boston, Chicago, Baltimore, Buffalo, Cincinnati, Cleveland, Grand Rapids, Pittsburg, St. Louis, Washington, Montreal, Ottawa, Toronto, and in London, England. Farms are operated at various points from which these laboratories are supplied. The plant at Plainsboro, New Jersey, is situated on the main line of Pennsylvania R. R., about midway between New York and Philadelphia, and furnishes milk to the laboratories in both the latter cities, from which private customers are supplied with milk and cream guranteed as to purity and fat content, and where prescriptions for modified milk are filled. This modification consists in varying the proportions of fat, protein and milk sugar according to the needs of infants and invalids.

The Plainsboro farms comprise about 700 acres of good land, mostly tillable, lying in one of the best farming sections of New Jersey. The improvements consist of good substantial fencing, and buildings for the proper accomodation of all the departments of a great dairy farm. The buildings have all been erected for use rather than show, but are tastefully built and present a most attractive appearance.

The German party escorted by Mr. C. E. Gordon was taken first to the silos. Of these there are three having a capacity together of about 1,200 tons. They are circular in form, narrowing toward the top, built very substantially of brick and coated on the inside with a mixture of coal tar. The silos are filled by a power blower from the shredding machine. Mr. Gordon explained that the grain fed, and most of the hay, were purchased, the Plainsboro farm providing the green fodder and ensilage; the latter is fed from October through the wtnter—ordidarily 20@25 pounds to the cow, the dry cows getting rather more. The last green food given is cow peas.

Overhead trolley provides easy means of transfering the ensilage from the silos to the cow stables near by, as well as for carrying the stable refuse to the manure distributing point where it is dumped from the big buckets directly into carts and spread over the land.

The cow stables are six, each having accommodations for about fifty cows; they are well and strongly built, of good height and provided with every convenience for sanitary operation. The high ceilings, rising to a gable roof in the middle, are whitewashed yearly; the floors are of cement, guttered behind the cows; the sides from about 4 feet above the floor to about 8 feet, contain glass sash, provided with hanging blinds, permitting ample light and air. The cows' stanchions are placed in two rows so that the cows' heads are toward the center aisle of the building. For bedding is used kiln dried shavings, which are procured in bales from the Standard Oil Works box factory at a cost of $4.50 per ton. Mr. Gordon said they had found this bedding very satisfactory. Stationary troughs, one for each two cows, are provided in which water is automatically supplied through connecting pipes and kept at a uniform level by a single ball valve in tank of even height at one end of the building. Over the head of each cow is a frame containing her individual record—when purchased, age, when tested, when served, amount and kind of food required; and behind each cow is another record of milk produced.

There are about 300 cows on the farm at present; they are selected without special regard to breed, though among them are several thoroughbred Guernseys, Jerseys and Holsteins, and pure blood bulls of these breeds. Calves are reared from cows whose product amounts to 10,000 pounds of 4% milk in a year. The company aims to keep only cows in perfect health; they are examined every two weeks by a veterinarian and any that may become sick are sent away. The present herd yield averages about 23 pounds daily, and the average fat test is 4.40.

In one of the stables are kept cows selected for infant feeding, the selection being made according to the character of the fat globules.

The visitors were investigating the stables at milking time, and were able to observe the care with which this work is done. The cow's tails and flanks are washed daily and before milking, the udders are washed whenever necessary. Twenty-six milkers are employed, each provided with white duck suits which are sterilized twice daily. The cows are milked in partly covered pails, previously sterilized, which are immediately emptied into larger covered cans standing at the end of the aisle; these, when filled, are placed on small flat cars that run on a narrow guage railway outside, by which they are at once transferred to the milk house, being elevated on an incline to second story. Then the cans are emptied into a large circular can through strainer cloths and cotton and the milk passes at once to a large porcelain vat where it is thoroughly mixed; thence over a large tubular cooler and directly to the bottling apparatus below. The temperature of the milk is reduced to 34 and 40° by the cooler and the milk is in sealed bottles at that temperature within an average of 12 minutes after being drawn from the cows. The bottles are then packed in boxes holding 12 quarts, covered with ice, and immediately taken to the rail road station. An Alpha DeLaval separator is used for separating such cream as is needed.

A room that is adjacent to the milk room is devoted to washing and sterilizing the bottles.

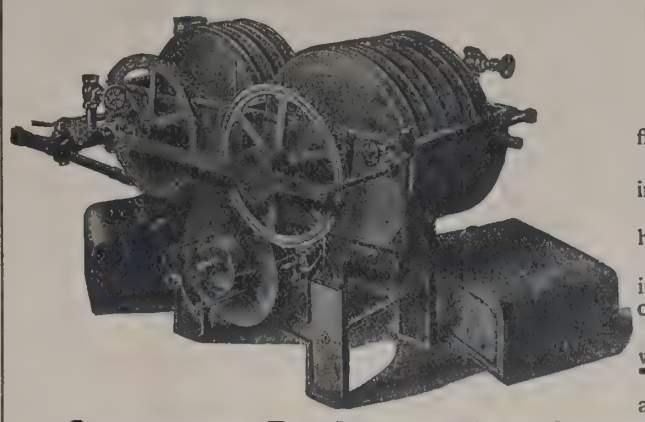
The German visitors seemed much impressed with the convenience and completeness of all the arrangements and seemed to regard the plant as a model of scientific milk production and handling.

Forage Crops to Supplement Summer Pasture and Winter Hay.

(Press Bulletin.)

Because of the long continued drouth the prospects are very unfavorable for the hay crop. While it is to be hoped that before this reaches the eye of the reader the drouth will have been broken by copious rain, many farmers will still need to grow special forage crops to supplement the summer pasturage or the winter's hay. While Indian corn is the best forage plant for Maine, if a sufficient acreage has not been planted, the season is so far advanced that other quicker growing plants can now be more advantageously used.

The millets—Hungarian, German, Pearl and Japanese, Rape, and on light, warm soils, early soy beans—are the more desirable. The smaller growing millets can be made into hay, the larger can be fed green, or made into silage. Rape is valuable as a summer and fall feed for cattle, sheep, hogs and poultry. The soy bean is highly nitrogenous, but Maine is so far north as to make it a somewhat uncertain crop. Those who need to plant supplementary forage crops, should send to the Secretary of Agriculture, Washington, D. C (do not inclose postage as the Department has free use of the mails), for the following Farmers' Bulletins:



No. 101. Millets.
No. 164. Rape as a Forage Crop.
No. 168. Pearl Millet.

Do not send to the Maine Experiment Station for these publications, as we can not supply them.

CHAS. D. WOODS, Director.
Maine Agricultural Experiment Station.

More About Milking.

ED. HOARD'S DAIRYMAN:—The articles in late numbers of the DAIRYMAN on milking are suggestive and should receive due attention from farmers.

The one in DAIRYMAN for May 15, written by L. O. Jackson, seems almost beyond belief. To think that there could be an increase in yield of milk of 9 gallons a day from 16 cows as the result of a change of milkers, when the first was considered good, while the second proved to be so much better as to get this great increase with other conditions the same, is enough to set farmers to thinking.

With such an experience as this, as an illustration, is it any wonder that cows dry up in milk when the class of milkers who have to be so largely depended upon is taken into consideration?

Time was—a generation or more ago—when there were more sons and daughters in the farmers' homes than now, and as a usual thing they all learned to milk. Now it is not common for women to milk, at least here in Vermont, and that is all right, as they have enough to do in the house, and the milkers are largely the hired help.

I live in an extensive dairy region where many cows are kept, where help is hard to be obtained and the question of milking is becoming a serious one.

It is, indeed, on these farms with large dairies, the most important part of the day's work, and needs to be attended to at the proper time and in the best manner.

The help is mostly hired by the month, season, or in uncommon instances by the year, just as it happens to be.

It is a good man who can be retained a year or more in one place, and, perhaps not as long. These frequent changes are bad when taken in connection with milking and should be avoided as far as possible, if the help is at all what it should be; if not, the sooner a change is made, the better it will be.

I think that if farmers would so manage as to have a certain number of cows given to each milker—that is the same cows—all of the time, it would be be much better than milking just as they come. This might require a little more attention, but it must be productive of decidedly better results. In this way the milker and cow will get used to each other, the cows will be more quiet and the milker, understanding the peculiarities of each cow, will know better how to get along with them. When the man and the cow are on good terms with each other, there will not be much trouble.

Quite a good many years ago there was a farmer living in Vermont who had a small, choice herd of Jersey cows which probably exceeded any other herd in the state in the production of butter. He had the entire management and care of these cows, and if possible, they were always milked by him. Under these favorable conditions, these cows did their best, and, as may be supposed, the owner was proud of them.

It happened one winter that the managers of the State Dairymen's Association desired to have him attend the annual meeting and give his experience with his cows for the benefit of other dairymen, but were under the necessity of so arranging that he go home in season at night "to milk his cows."

Here was one secret of his success, he milked his own cows and the work was well done.

Regularity in milking should also be considered, for cows as well as men are the creatures of habit. If possible the intervals between milkings should be about the same, as this will be better for the cows when giving large amounts of milk.

One night while attending a Farmers' Institute in winter, I stopped with a farmer who had a fine herd of Jersey cows. After getting home from the evening meeting, between 9 and 10 o'clock, what did he do but take his pail, go to the barn and milk. He must have done this work alone, as it would be difficult getting hired help to assist at that time of night. I do not remember at what time they were milked the next morning.

This is a practice we would not advise others to follow.

I have a farmer friend who is about 75 years old. His father had a large farm, milked many cows, and made money with cheese at 5 to 6 cents a pound. This man when well, has always milked. He now, at his age, averages 17 cows night and morning, and sometimes has milked 20. He must be a natural milker, but it would seem that this number is too great even for a much younger man.

The milking should be made as pleasant and agreeable a part of the day's work as circumstances will permit, and then there will be less difficulty with it.

It is well to commence the day's work early in the morning, but it should be the endeavor to get through equally early at night. There is nothing I think that will discourage the boys or hired help more than being constantly late with the milking and other chores at night. This doing a full day's work on the farm and the chores afterward, is not a practice to be commended or that will work well.

Franklin Co., Vt. E. L. TOWLE.

Important Notice to Owners of Holstein-Friesian Cows.

At the annual meeting of the Holstein-Friesian Association of America, held at Syracuse, N. Y., June 3, 1903, the following changes in the rules of Advanced Registry and official testing were made:

1. Requiring that a period of at least six days shall elapse after a cow drops her calf before an official test shall commence.

2. Requiring that the computation of butter from butter fat shall be made by adding to the amount of fat one-sixth of said amount, which shall then be given in pounds and ounces. This computation shall be made by the Superintendent of Advanced Registry, and the experiment stations shall be held responsible for only the amount of milk and butter fat reported by them. The requirements of butter fat to admit to entry in the Advanced Registry remain unchanged. For a cow calving at two years, or under two years of age, the minimum requirement being 7.2 lbs. butter fat in seven consecutive days; for a cow calving at just three years of age, 8.8 lbs.; for a cow calving at just four years of age, 10.4 lbs.; for a cow calving at five years of age or over, 12 lbs. Every day of increased age at date of calving from two to three years, from three to four years, or from four to five years increases the requirement, .00439 of a pound per day.

3. The system of economic testing heretofore maintained is abandoned and in its place a requirement is made that in all cases in which the production of butter fat in seven consecutive days is 18 lbs. or more, the owner shall report, in connection with the production, the kinds and amounts of food consumed by the cow during the test, to his best knowledge and belief, under oath.

4. Prizes for seven-day records and thirty-day records for the year commencing May 6, 1903, and closing May 5, 1904, are as follows:

FOR SEVEN-DAY RECORDS.

PRIZES.

Crops For Late Planting.

Advice From Missouri Experiment Station —Not Yet Too Late to Secure a Good Crop.

The unprecedented rains have destroyed wheat, rye, oats, and corn in many localities of the State. It is not yet too late to secure good yields of several valuable forage and grain crops. Only seventy-five per cent of the corn has so far been planted in the State. There is yet time to plant corn, and with an average season secure a fair yield of grain. The following suggestions are offered at this time to farmers who failed to finish planting corn before the rains, and also to those whose crops have been destroyed by washouts, floods and overflows. The stock farmer especially can by good management even at this late date produce an abundant and sufficient supply of valuable feed for animals. The purely grain farmer is not so well situated under the present conditions to get the most out of his land.

PLANT CORN UP TO JULY IST.

Farmers will be urged to try many

S. E. NIVIN, Landenburg, Pa.

sorts of new forage and grain plants which are recommended to be far better than corn. This Station advises all farmers to plant corn in every case where the conditions allow this to be done before July 1st. The most important factors in securing a crop when planted so late, is the selection of the right variety. Select in every case that variety of corn which will mature earliest in your locality. Some early maturing varieties of corn that can be recommended are Pride of the North, Riley's Favorite, Reid's Yellow Dent, and any variety of Flint corn. Any one of these varieties will yield more grain or forage in Missouri than almost any other forage crop, if planted before July 1st. These varieties should be planted somewhat thicker than the varieties usually grown in Missouri.

SORGHUM AND KAFIR CORN.

These crops are grown extensively every year in some sections of Missouri. They yield a large amouut of forage, and if planted before the first of July they may also produce a good yield of grain. The best variety of sorghum for Missouri under the present late conditions is the Early Amber. For bottom lands we recommend the Early Orange which stands up better. This should be planted in rows about 3 or 3½ feet apart. The most practical way to plant sorghum, is in the ordinary corn planter, using the broom corn discs. It can also be planted with a disc or shoe drill. On rich lands it should always be planted in rows. On poor lands it may sometimes be advisable to sow broadcast. Kafir corn is successfully grown, especially in Southwest Missouri, and may be grown with profit in other sections of the State. For the production of grain, kafir corn is to be selected always in preference to sorghum—for forage only, sorghum is probably better. The best varieties of kafir corn are the red kafir corn and the white. At the Kansas Station it was found that kafir corn yielded from 30 to 58 bushels of grain per acre, and the grain was nearly as valuable as Indian corn for fattening cattle and hogs. The seed, if planted by drilling, should be sown at the rate of six pounds per acre.

COW PEAS.

Cow peas have been grown successfully in every section of the state of Missouri. The best time for planting them is from the 15th of June to the first of July. They can be planted as late as the middle of July. The yields of hay from cow peas planted on good soil, are from one and a half to three tons per acre. This hay is as valuable as clover hay, for all purposes of feeding. The best varieties for Missouri are Clay and Whippoorwill for hay, and the New Era, Warren's Extra Early, and Red Ripper for grain. If cow peas are planted immediately, it will be possible to cut them for hay during the last week in September and by discing the ground thoroughly, put it in splendid condition for wheat. Where it is desired to sow submerged lands for wheat in the fall, this will be found altogether the most satisfactory method.

SOY BEANS.

This crop furnishes one of the most valuable grains for feeding purposes that can be produced on the average Missouri farm. The yield of soy beans is from 20 to 30 bushels per acre. They can be planted in June at the rate of half a bushel per acre. They should be planted in drills about three feet apart. They can be harvested by pasturing with hogs or they may be pastured with other animals, or they may be harvested for their grain. The average two-horse corn cultivator may be arranged with two inclined knife edges which will cut two rows at a time. After drying, they may be raked up and stacked and the stack covered with some material that will shed water, or placed in the barn. They can be threshed in the ordinary threshing machine by removing part of the concaves. The grain from soy beans contains a larger per cent of digestible protein than any other of the grains grown on the farm. This makes this crop peculiarly valuable to be fed with corn.

Every farmer who has land that has not been planted on account of the recent rains, should plan to put in some of the crops suggested above. It is not at all necessary that the land should lie idle, and Missouri may yet produce a maximum crop. The Station will upon application gladly give more detailed information regarding the production of any one of these crops.

LOOK HERE.

34 cows and heifers in the McGEOCH HERD have been officially tested with the following results: 10 cows average 20.26 lbs. butter in seven days; average per cent of fat 4.06. 7 four-year-olds average 16.82 lbs. butter in seven days; average per cent of butter fat 3.93. 9 three-year-olds average 15.06 lbs of butter in seven days; average per cent of fat 3.50. 8 two-year-olds average 12.16 lbs of butter in seven days; average per cent of fat 3.60. We have a few young bulls out of some of these cows, and sired by Gem Pietertje Hengerveld Paul DeKol, or Sir Ormsby DeKol for sale. One of these is out of a cow that made official record of 24.88 lbs. of butter in seven days, average per cent of fat 4.47. Are these the kind of Holstein-Friesians you wish? If so, can we not interest you in putting a bull from this class of stock at the head of your herd? McGEOCH HERD is located at Lake Mills, Wis., 56 miles west of Milwaukee. For particulars address H. B. Daggett, Mgr., Station A, Milwaukee, Wis Residence: National Ave. near 40th. Phone, South 1601

The Relation Between the Nurseryman and His Customers.

[Abstract of talk by J. H. HALE, South Glastonbury, Conn., before the American Association of Nurserymen, Detroit, Mich., June 11th.]

Owing to the nature of the business and the fact that the real value or purity of many varieties of nursery stock cannot be known for some years after planting, the nurseryman, aside from being a most conscientious and careful propogator, is in honor bound to act as a counselor and friend of the planter. The most successful lawyers are those who aim to keep their clients out of lawsuits and other troubles, and so the nurseryman, who wants a profitable and permanent business, can find no surer way to success than by guiding intending planters towards the purchase of most suitable varieties, regardless of any surplus stock he may have of less desirable sorts. To be sure, many nurserymen at the present time do not know as much about varieties, suitable locations, methods of culture marketing, etc. as they ought. The demand for cheap trees and plants has forced him to hustle in the production of greatest number of trees and plants at least possible cost, and the average customer is not willing to pay for anything but the bare cost of the trees. And so it is that there are far too many nurserymen who could not tell at sight the fruit of many of the varieties they propogate.

The vast majority of nurserymen are honest, careful men, yet being human they do make mistakes and when once a mistake is made the continued propogation by taking buds and scions from the planter or nurseryman, who gets his stock that way, is not on the road to success and will never cut much figure in the market. Frequent visits to fruiting fields and orchards of successful cultivators, will supplement the information obtained from our own test plots and those of the Experiment Stations, for the nurseryman should be a walking cyclopaedia of horticultural information, always on tap for the benefit of his own customers and those of the other fellow also. The more horticultural information we can circulate, the larger and better will be our business.

One of the largest items of expense in my office is correspondence on horticultural topics that do not pertain directly to the nursery sales, and I count it profitable advertising to furnish information to all who inquire, even to the extent of explaining how to prune, plant and care for a lot of trees bought from another nursery. There is something wrong in a nursery that is always seeking new customers.

Old customers should be our best ones, and will be, if care is taken to always give them the best stock you have and never sell them a variety you would not plant yourself. Nothing pleases a man more than to show his friends his lawn, garden, field or orchard giving satisfactory results of bloom or fruitage, and if by judicious advice in planting you have started him on the road to success, the fruitage of his plants and trees and his constant talk are all in your favor; a standing advertisement, "fully illustrated, top of column, next to reading matter."

If a customer asks for Ben Davis apples, Keiffer pears, Snead peach, Gold plum, Ada Strawberry, or other like truck, and says he knows what they are

Holstein Cow, Sadie Vale Concordia.

Premiere Holstein-Friesian Cow. Property of MC ADAM & VON HEYNE, and to be included in their sale of July 15th.

nursery row, increases the error and we are sending out mixed varieties, causing no end of trouble, both to the nurseryman and planter.

It may cost a little more to take our buds and scions only from fruiting trees of known value, but it insures purity and tends to breed up rather than down. My orchard interests being greater than my nursery interests, I know and feel these things from the planter's point of view, and I am sure there is a generation of planters growing up who will gladly pay any extra cost of propogation to the nurseryman who will always propogate from fruiting stock.

An experimental test field and orchard is a very expensive adjunct to a nursery, but it is absolutely essential where one has not other means of keeping fully posted as to varieties.

Our Agricultural Experiment Stations are doing considerable of this class of work, yet ought to do ten times as much as most of them are now doing, and do it better too; and if they have not funds enough to fully do the work it is our duty to see that our Legislatures make more liberal appropriations and also our duty to furnish the Station freely all new trees and plants a few years before introduction if possible. This might hinder the sale of the great Hunkedory pear, Bouncing Bet strawberry, or Aaron's Dewy rose, yet be of real encouragement and value to intending planters and to the business interests of the legitimate nursery trade. I know that in a few instances in the past, that plants, buds and scions have passed out of the hands of the Experiment Station people without proper authority. To my notion the and yet wants them, it may not be a crime to deal with him, but to work them off with colored plates on unsuspecting victims in any section of the country where better varieties may be grown, is an injury to the buyer and a blow at the nursery trade. It should be the aim of the nurseryman to know as much as possible of the soil and climatic conditions in the section of country where his customers reside, otherwise he is not in position to recommend varieties most suitable to successful culture. Nursery sales agents who are lovers of plants and trees and who keep up to date in varieties and methods, are true missionaries of horticulture, helping the ladies out on pruning roses, telling them how to rid their plants of insect pests and by being generally useful at the right time and by traveling in the same territory year after year have wonderfully stimulated horticultural thought and practice, to their own profit and the public good, while the fellow with picture books and big stories, selling so-called novelties at high prices is no permanent help to the legitimate nursery trade or the cause of horticulture.

While it is true that nursery agents blaze the way in new territory and tempt many people to buy in a small way, everywhere, yet as soon as people become well interested in horticulture there is more and more direct dealing between planters and nurseymen, saving in cost to the one and increasing the profits of the other, and for the continuation of this mutual benefit arrangement, the nurseyman must by education, training, thought, and practice be a leader among men, one whom planters may look up to with confidence.

In our annual convention we trade too

WE TAKE THE RISK
of your being satisfied, and glad you bought the cream separator that makes money for you.

much in trees and plants and not enough in ideas. We cannot help others without helping ourselves more, and so anything that we can honestly do to help the planter to greater pleasure and profit will surely help the nursery trade. Don't be selfish about it either, help any and all you can, you cannot possibly be of help to others without enriching yourself.

Make your catalogue a hand-book of up-to-date useful information, do a little more than you agree every time. Many trees and plants fail to make a satisfactory start through lack of proper pruning at the start; I find it a good plan to send out with my orders a few specimen plants properly pruned root and top. Customers often think I overdo the matter, but final results are so satisfactory that they are sure to come again and stay permanent customers. A little extra care in packing, a little stronger cord, a little more moss, straw or burlap will add a little to the cost of packing, and sometimes a little soaking of the bale itself before shipment may add to the cost of freight or express and the customer may be a litle excited when he pays the bill, but when the trees and plants begin to grow and show the results of these little extra attentions, everybody is happy and business is on a firm foundation.

You can't satisfy everybody, but it pays to keep trying. The perishable nature of trees and plants, when out of the ground, makes it almost impossible to deliver many trees and plants in the same good condition as when they leave the nursery. Then the handling by the planter and his soil conditions have much to do with results.

A few years ago I shipped some 40,000 small fruit plants to two customers on the same day, plants of mostly the same varieties, dug from the same field on day of shipment, handled and packed by the same men all the way through, and shipped away on same train and delivered to both parties three days after. A little later, when they came to pay the bills, one customer praised the plants, liberal count, and good packing and told of his fine fields of growing plants. The other said, while he had been swindled before by nurserymen, this was the worst of all, not over ten per cent of his plants were alive and wanted to know what I was going to do about it. Of course I had to shoulder most of the loss, but tried to get even by telling him to prepare his land better next time and exercise greater care in handling plants, which he will, no doubt, buy of the other fellow.

Last year I had an exceptionally fine lot of peach trees of large size and fine form and sent them out to my customers with great satisfaction, and so was a little chagrined by receiving in one day's mail, two letters, one complaining of the "small sized, inferior trees," and the other saying "no use for trees big enough for saw logs."

A gentleman in New England, starting a large orchard property, placed an order for 3,000 peach trees with a very reliable nursery firm in New York, leaving them to select the varieties. They sent him a splendid lot of trees, yet of varieties utterly unsuited to his location.

One variety of 200 trees is paying a profit, the other 2,800 have been cultivated at a loss and the man is discouraged and the nursery trade suffers, all through the failure to have a little "spot knowledge" to throw in for good measure with the trees.

Don't sell a Bosc pear, or Crawford peach to be planted on sandy lands if you can help it. Aim for successful results in all tree planting, help to make the business of your customers successful and profitable and you will have done more to advance our nursery interest than can possibly be accomplished in any other way.

Alfalfa in the South.

Inoculation of alfalfa seed and soil seems to be a perplexing question. There are several conditions to be considered and then the practical applications of the scientific facts are made plain to the farmer. The germ of the alfalfa nodule grows best in alkaline media and grows poorly or not at all in acid media. Hence acid soils (sour soils) are not suitable for the growth of alfalfa unless they are changed from acid to alkaline, or the soil be made rich in plant foods, especially nitrogen. All lime lands are alkaline in reaction and are consequently most suitable for the growth of alfalfa. Recently I saw specimen plants from a ten acre field of alfalfa which was sown in the fall (rainy autumn) and in four weeks the plants had an abundance of tubercles on their roots. No inoculation was made, but the land was a rich, black lime land. This was done by Dr. McCain, of Sumter county, in the Western part of Alabama in the black lime belt of the State.

Some one may say that there were germs enough on the seed to inoculate lime land. If so, no inoculated soil is required. At any rate the quantity of soil required for inoculating lime lands is greatly exaggerated and possibly in most cases not required. A limited experience has led me to conclude that 100 pounds of inoculated soil, thoroughly pulverized aud sowed or drilled with 20 to 30 pounds of alfalfa seed, will thoroughly inoculate any alkaline soil.

The reaction of the soil may be known by the presence of lime rock or tested by the use of blue and red litmus paper. When moist alkaline soil is placed on red litmus paper it will cause the red paper to become blue; when on blue paper the color will not change. Moist acid soil will turn blue litmus paper red and will not change the color of red litmus paper. Litmus paper may be purchased of the druggists.

Liming land may change it from acid to alkaline in reaction. Usually, acid soils require from 10 to 20 barrels of lime per acre, in order to make them alkaline, and it may not be necessary to relime the land for years, the time depending on the chemical combinations made in the soil by the lime and the rapidity and rate of leaching or washing out of the lime by the rains.

All the rich lime lands of Alabama are good alfalfa producing lands. The poor eroded lime or bald spots or patches should be brought up by using mellilotus, or sweet clover, because it will grow better than alfalfa in such places, produces fairly good pasture and the first year it will produce better hay than Johnson grass or timothy, if cut at the proper time.

According to the experience of Dr. McCain, alfalfa may be grown on rich lime land where Johnson grass has partially taken possession. On such land sow it in the fall, and if the rains are early and sufficiently frequent and heavy frosts do not come until late in December, the alfalfa will get a good start in the fall and winter, so that the hoar frosts of winter cannot lift it out, nor the growth of Johnson grass choke it out in the spring. During the first spring and summer, cut it as often as the Johnson grass begins to exceed the alfalfa in growth, and disk after every cutting. When the rains are good and the frosts are not too early, fall sowing of alfalfa gives it a good start of the weeds during the following spring. In that sense fall sowing has the advantage over spring sowing, but spring sowing on rich lime land with good and sufficient rains will make one or two good cuttings the first year.

Let me suggest that Alabama or Southern farmers who have indestructible Johnson grass, try sowing hairy vetch in August or September right in the Johnson grass without disking or plowing. If the land is rich lime land and fall rains are good, the next May will show a sight fit for the gods.—C. A. CARY in *Breeder's Gazette.*

T. D. Goodwin & Co.,

USE GOODWIN'S FLY KILLER

this season and make your stock comfortable. Your cows will give 25 per cent more milk; your beef cattle will fatten with one-half the feed and your horses will do their work with ease. Goodwin's Fly Killer will protect stock from flies when in pasture as well as in stable. It's convenient, cheap, practical. It's a sure lice killer and will keep stables and hog pens in a sanitary condition. Prices: Gallon 75c; 5 gallons $3.00; 10 gallons $5.50. Good sprayer for applying same 50c, or send $1.00 for Sprayer and enough Fly Killer to protect 150 cows. Agents wanted. **T. D. GOODWIN & CO., Columbia Station, Ohio.**

Chloro-Naptholeum Dip

HOG CHOLERA is the bane of the swine raiser. It must be **PREVENTED**—that is the only absolute **CURE.** The first and only safe course for the maintenance of health in your hogs is to obtain **Chloro-Naptholeum Dip,** the great stock remedy, and our **FREE BOOK** on Swine Diseases, which gives full directions for using it. **USE** the Dip at once and freely and also **FEED** it to your swine in the slops and drinking water, disinfecting them inside as well as out. It is strictly non-poisonous to the hogs but will absolutely cure them of lice, mange or itch and prevent **HOG CHOLERA.** Lice transmit disease from animal to animal. **Chloro-Naptholeum Dip** is the most widely used preventive of Hog Cholera in existence. *Hog Cholera is unknown where* **Chloro-Naptholeum Dip** *is used regularly.* It is the safest dip and the easiest to use, requiring no heating or other preparation, coming to you **CONCENTRATED**—just put a little in a lot of water. Prices, freight prepaid: 1 gal, $1.50; 5 gals, $6.75; 10 gals. $12.50. Larger quantity at lower rates. **LOCAL AGENTS** will find a greater profit selling **Chloro-Naptholeum Dip** than any other article by the liberal terms we offer. Write us. We sell dipping tanks and sprayers at special low prices to our customers. Don't buy or build till you get our prices. **WEST DISINFECTING CO., INC., 8 E. 59th ST., NEW YORK.**

Coralette's Son, 3987.

Now Eight Years Old but Sound and Vigorous.

This Guernsey bull was bred by and is owned by George C. Hill & Son, Rosendale, Wis. He was sold as a calf to Rather & Beyer, two bright young dairymen of Calumet Co., Wis. Messrs. Hill bought him back in March, 1902, so his oldest, pure bred calves were dropped in January, this year. He was sired by Viscount 2177, the sire of Countess Bishop, 499.9 lbs. fat with second calf, and out of Coralette 5722, with a record of 479.7 lbs. fat in a year, commencing at 3½ years old.

She was first prize cow at the Wisconsin State Fair in 1896, and Mr. C. P. Goodrich in reporting that fair had the following to say of Coralette: "Of cows three years old and over, there was a splendid show of eleven. It put the judge, Mr. H. C. Taylor, on his mettle to make a decision in this case; but he went at the job in a workmanlike style, carefully and deliberately, never overlooking any essential point in any animal. He finally settled on Geo. C. Hill & Son's five-year-old cow, Coralette, as entitled to the first. When the onlookers, who were interested in dairy stock, came to look her over, they all said, "That's right. She is a splendid animal, perhaps a trifle too thick in the neck to suit the ideas of some, but that is the only fault anybody could posslbly find with her. She has the thin shoulders, deep body, strong back, thin thighs, and splendid udder of the true dairy cow."

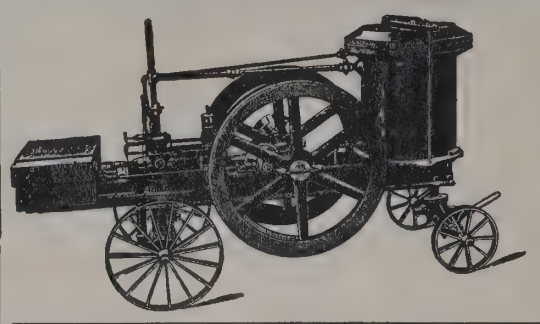
This cow was one of the best daughters of the well-known bull, Benjamin, who sired ten cows that made over 343 lbs. of fat. Her dam was Coral of Paulsdale that made 16 lbs. of butter in a week, and 369.2 lbs. fat in a year. Her grandam was Coralie, and great grandam, Coral 2d

Viscount, the sire of Coralette's Son, was equally well bred, but in different lines, and the Messrs. Hill are to be congratulated upon his return to their herd.

GUERNSEY BULL, CORALETTE'S SON, A. G. C. C., 3987.
Property of GEO. C. HILL & SON, Rosendale, Wis.

Conditions in Northern New York.

ED. HOARD'S DAIRYMAN:—It may be of some interest to your readers in other states to know how we are and have been faring for the past two months in central New York. March was warm and quite an amount of plowing done; the fore part of April was excessively wet, three weeks of mud which left the soil in a heavy, sodden shape, and from about the 15th of April no rain has fallen to wet the soil to the depth of one inch (and only two at that, and they were local) until June 12, last night, a northeast rain set in and has rained all night and is now raining hard at 8 a. m.



The damage to crops can better be told at the harvest, but it is safe to estimate the damage to the hay crop in Cayuga Co. alone at over one hundred thousand dollars unless we can get a second cutting. Many had already turned into meadows to keep their cows from going dry. Some few who had plenty of hay and silage have kept their cows up, but the great majority turned out their cows early to save feed bills and have, perhaps, a little hay to sell, as it has brought a very remunerative price, and plenty of hay has been sold recently for feeding that could otherwise not be sold at all.

Many farmers have not a furrow plowed for corn, very little corn planted, and much of that will have to be planted over again and many pieces that were sown to oats will be worked over, and be put

into corn and Hungarian for stock feed, but mostly at present time will be an extra effort to grow all the corn possible.

It has been very discouraging to our farmers to read in the papers of the excessive wet in the west and our teams standing idle because the ground was so hard they could not plow. We have the promise of seed time and harvest, but at the present outlook it will be the lightest harvest in New York state known by the oldest inhabitants. One neighbor, who is in his 92nd year, says he never saw the like, but this heavy rain puts fresh hope in our minds. A. D. BAKER.

Auburn, N. Y.

Pasteurized Whey.

ED. HOARD'S DAIRYMAN:—How much better is whey that has been pasteurized for the feeding of calves and hogs than the whey that is left to sour? G. B. C.

Richland Center, Wis.

Whey that is left to sour has a very much lower feeding value simply because it is not clean and wholesome food. The bacteria that grow in sour, unclean whey tanks will produce stomach troubles when the sour whey is fed. Besides, the bacteria produce compounds in the fermenting whey that are more or less poisonous when fed. This does not mean that slightly sour whey is dangerous, but whey that is slightly sour easily goes over into whey that is more than sour, and it is best not to take the chance of producing an unhealthy article. Heating the whey obviates all this and gives a clean, healthy food which the other conditions do not.

CONCERNING OUR ADVERTISERS.

Every one knows that a horse with the heaves is depreciated from $25.00 to $50 00, and some people would not take a horse with the heaves as a gift. Heaves is a disease which is liable to attack even the most valuable and best conditioned horse. It is well to have a known effective remedy on hand. Such a remedy is undoubtedly to be found in the Prussian Heave Powders, manufactured by the Prussian Stock Food and Remedy Co., St. Paul, Minn., whose advertisement we are running in another column. Many telling testimonials from users have appeared from time to time in these columns. It is one of a number of valuable preparations by the same company, which includes Prussian Stock Food, Poultry Food, Lice Powders, Lice Killers, Cough and Distemper Cure, e c. A good book explaining all the above is the 68 page Farmer's and Stockman's Manual, which, as indicated in the advertisement, is mailed free if you write the Company how many head of ctock you have.

The Havana Metal Wheel Co., Havana, Ill., announce in our columns that they "lead the world" as manufacturers of grooved and plain tire steel farm wagon wheels. They also guarantee their patented grooved tire wheels to be the best made by anybody anywhere. They are able to fit any sized skein. Our readers should write, if interested, for their directions for measuring axles for metal wheels.

A LESSON OF THE TIMES.

It is a very neat and attractive hanger in several colors and halftone effects, handsome enough for home decoration, which the Studebaker Bros. Mfg. Co. are sending out under the above title. It would be more aptly described as a pictorial history of the rise of a great manufacturing establishment. The upper panel pictures the unpretentious but now famous Studebaker blacksmith shop of 1852—the bud in which was wrapped up the brilliant Studebaker future. For it was this humble shop that by growth, development and enlargement is the logical predecessor of all that the great plant now boasts. Following this is an excellent reproduction of the plant as it now is, with the legends "Largest in the World" and "Plant Covers 101 Acres." Below are tastefully grouped the five Studebaker Brothers whose faces have become so familiar, and from a cornucopia on either side of this groupe comes all manner of vehicles, typical of the endless stream which flows from the Studebaker factory to all corners of the earth. This hanger, 20x38 inches in size, tinned top and bottom, may be had by writing the Studebaker Bros Mfg. Co., South Bend, Ind., and enclosing six cents in stamps to pay postage. It ought to be in every school house in the land.

FARMERS SAW MILL, $125.00.

The DeLoach Mill Mfg. Co., Box 112 Atlanta, Ga., who manufacture every description of modern saw mills, in all sizes, are offering an exceptional bargain in their Farmers' Saw Mill at $125. This will cut 2,000 feet of lumber per day with only four-horse power. So great is the popularity of this mill that its sale has extended around the world, not only into Alaska, British Columbia, and Mexico, but across the sea to Europe, Asia, Africa and the islands of the sea. Their handsome catalogue will be sent free to our readers who request it, and is highest authority on the subject of which it treats.

RURAL TELEPHONES.

Telephones are becoming very common in rural communities, and the more they are used the greater their appreciation. The low cost of maintaining a service of that kind makes it possible for those who are in even very moderate circumstances to have telephone connection with their neighbors and with neighboring towns. It may safely be said that the telephone has solved more problems than any other invention of modern times. It has made farm life more attractive and brought into close communication those who have formerly been widely separated. It is now a common thing to have daily conversation with friends or relatives who live many miles away and where formerly exchange of friendly greeting or consultations concerning business was a matter of considerable time and a journey of several miles, it is now a matter of minutes and of going to a telephone in the house. In the matter of business alone any farmer can well afford to pay the small cost of a telephone, for there will be dozens of times during the year when he can make or save money by being in almost instantaneous touch with his market town. Putting in operation a telephone line is very simple. Any one can do it, and it requires no special skill to keep in repair and operate a line. There are numerous makes of telephones for rural lines on the market, but the ones made by the Stormburg-Carlson Telephone Mfg. Co., Chicago, Ill., is having the largest sale and is giving the best satisfaction. This is one of the oldest houses in this line in the country, and the telephones made by this company have been found to be perfect in their adaptation to the uses of people in country places. The company publishes a very interesting catalogue and we would advise our readers to send for one, and see for themselves how easy it is to "get on the line." Address Stromberg-Carlson Telephone Mfg. Co., F15, Chicago, Ill., and do not forget to say we invited you to do so.

VETERINARY.

Queries in this department answered by DR. A. H. HARTWIG, Watertown, Wis.

Infectious Abortion.

I have eight cases of abortion in my herd. Can you give me your idea of how to treat it?

Port Arthur, Tex. J. C. M.

ANSWER.

We must, first of all, isolate the cows which have aborted: destroy the afterbirth and foetus, and thoroughly disinfect the stables in which they have aborted: whitewash the walls and give plenty of light in the stables. About the best agent to apply to the floor is air-slaked lime. Apply it once daily after cleansing. In the absence of lime, wood ashes or land plaster may be used instead. If in the grass season it is advantageous to put the healthy cows to pasture. The cows which have aborted should not be allowed to retain the after-birth; the same should be promptly and completely removed, and the uterus and vagina thoroughly cleansed by irrigating same with a 1-5000 solution of bichloride of mercury, or other disinfecting agents. This can best be done by using a large-sized fountain syringe, and should be repeated once daily, until the disappearance of the vaginal discharge. Until this has entirely disappeared no cow should be used for breeding purposes, or be allowed to be returned into the herd among the healthy cows. We may also increase the power of resistance of all the animals by means of food rich in nitrogen, and a teaspoonful or two of powdered cramp bark in food, once daily.

This is a very important question to the dairymen, but it seems they have paid very little attention to it heretofore, as the same question is being asked almost every week. Many prefer to try patent medicines taken internally and others inject them hypodermically into the connective tissues to be absorbed by the blood, and maintain the idea that through these sources they may obtain relief. While it is generally accepted that the disease is caused by a specific germ which confines itself to the vagina and uterus and remains there for an indefinite time, even after abortion has taken place, would it not seem reasonable that we should seek relief through these channels by applying antiseptic agents directly to the seat of the trouble, thereby destroying these germs and preventing their accumulation in the first individual which aborts in your herd, and preventing the disease from going any further?

NOTHING SO GOOD

has ever been presented to the public and which has been of such wondrous merit as

Kendall's Spavin Cure.

It is the old reliable remedy for Spavins, Ringbones, Splints, Curbs and all forms of Lameness. It cures without a blemish because it does not blister. Price $1. 6 for $5. As a liniment for family use it has no equal. Ask your druggist for KENDALL'S SPAVIN CURE, also "A Treatise on the Horse," the book free, or address DR. B. J. KENDALL CO., Enosburg Falls, Vt.

CURE "THE" COW

NO CURE, NO PAY

WRITE, giving symptoms of animal sick, and will ship you by express quantity sufficient to cure your cow with full directions for use. If I do not cure the animal the advice and Cure "the" Cow costs you nothing except the express charges. If I do cure it you can send Postal order for cost of the remedy—$2.00 per quart, $3.50 per half gallon, $6.00 per gallon and pay for what you use. Generally half a gallon cures the worst cases. Give Postoffice and Express office with your order. Address

DR. EATON J. CROSS,
152 Congress St., Troy, N. Y

An Appreciative Trial Subscriber.

Yield of Cheese From 4 per Cent Milk.

ED. HOARD'S DAIRYMAN:—I enclose $1 for which please extend my subscription to the DAIRYMAN. I am one of your 5 month's trial subscribers. Words can not express my appreciation of your valuable paper. I am sorry that I did not become a subscriber sooner. I run a dairy of twelve cows, a mixed lot, two pure bred Jerseys, some others that contain quite a lot of Jersey blood, one Holstein, and a few grade Durhams, and sell milk and some cream to retail trade. I farm some in connection with my business, have no silo, but by good feeding in winter and proper housing and other attention to details and good pasture in summer, make my 12 cows average upwards of 225 pounds of milk per day, the year through. Besides our own use of milk in small family, I sell $1,200 worth of milk and cream per year.

I am thinking of increasing my business and as I have no more market for fresh milk and cream, would you be so kind as to tell me through the DAIRYMAN how many pounds of cheese from 100 pounds of whole milk, testing 4% butter fat, I might expect? I have a fair idea as to what I could realize from butter, but don't know anything in regard to the amount of cheese I could make from 100 pounds of 4% milk. If not too much trouble, give me an estimate, please. J. L. B.

Rolla, Mo.

Letters of the above character are not only gratifying to the editors, but they should prove a strong incentive to readers to inquire why they may not do as well or better than J. L. B. is doing. Good feeding, proper housing and other attention to details enable him to secure $1,200 a year from twelve cows. If we allow that it costs half of this gross income to deliver the milk and cream to customers, there still remains a net income of $50 per cow. We believe this might be increased at least 50% if still greater attention was paid to selecting out, and keeping the best cows and disposing of those that do not come up to the proper standard.

Answering the specific inquiry, we may say that a few years ago, Prof. John W. Decker, now of the Ohio Agricultural College, made 11.4 pounds of green cheese from one hundred pounds of 4 per cent milk at the Wisconsin Dairy School. This cheese in curing would certainly have lost not more than one pound, leaving 10.4 pounds cheese fit for the market. Whether our inquirer can obtain this yield will depend somewhat upon his skill and the appliances provided for manufacturing the cheese.

Inoculating for Alfalfa.

The recent discovery of successful methods of growing alfalfa will probably lead to the seeding of many fields to this legume during the present season. I seeded a field of four acres last year and met with both marked success and complete failure—success in that portion of the field where the soil was inoculated and failure where there was no inoculation. My field was thoroughly prepared and a very even stand obtained. At the time of seeding I sowed about one acre across the field with soil infected with alfalfa bacteria, or, in other words, with soil in which alfalfa had grown successfully, with its root tubercles in abundance.

I applied about 100 pounds of this soil to the acre, The whole field grew well during the summer and root tubercles were found in abundance six weeks after seeding, on a small part of the infected acre where the infection had been very heavily applied. As the season advanced the infected acre began to show more thrift and at the end of the season was noticeably larger than the uninfected parts. This spring the field presented on May 10, a most convincing proof of the absolute necessity of soil inoculation. The growth of the alfalfa on the infected acre had exceeded our most sanguine expectations. It is of a dark green color and making an enormous growth. The drainage has carried the infection in streaks and spots to the lower parts of the field, all of which show the same luxuriance. The division line separating a narrow strip of uninfected land on the upper side of the field toward which there has been no drainage, is as distinctly marked as the boundary of a field. On those portions of the field where there has been no inoculation the alfalfa has been of a pale yellow color and very much of it so feeble and stunted that it will soon die out unless assisted. I have procured more soil with which to inoculate these remaining parts of the field.

I would urge those who attempt to grow alfalfa to go at it in the right sure way; do not take chances. Where one man will succeed without systematic inoculation a score of men will fail. To depend on the infection which is in the seed is too hazardous and too expensive and usually entails the loss of the first seeding with the consequent loss of the use of the land and labor for the year.

Infected soil can be procured for 50 cents per 100 pounds and the freight added. This is enough for an acre. I procured both lots of soil that I used from the Illinois Experiment Station. It may be procured from well-established alfalfa fields where there is an abundance of root tubercles. There is no great mountain in the path; just get the infected soil and sow it broadcast, by hand if you like, one handful at a throw; sow at the time of seeding and harrow it in; the little fellows in the dirt will do the rest.—RALPH ALLEN, in *Breeders' Gazette*.

Skim Milk Returned.

How much skim milk is returned to the patrons of co-operative creameries where just the cream is bought and is it usually returned by weight or measure? F. M. C.

Silcett Springs, Va.

Skim milk is returned to the patrons by weight. The amount of skim milk to be returned depends somewhat on how much cream is taken, but as an average 80 pounds of skim milk is returned for every 100 pounds of milk delivered.

234 ACRE FARM FOR SALE

One-half mile from Janesville, Wis. New 12 room house, good barns, etc. Fine black soil. A great bargain and if taken at once the purchaser gets the rent. It is one of the best farms in the famous Rock River Valley and will be sold on easy terms to a good man.
WILSON LANE, Janesville, Wis.

P. O. Box 144, Charlottesville, Va.

Buy You a Ticket to CROOKSTON, MINN., and call upon
The Polk County Land & Loan Company

For choice Red River Valley Farms. They pay railroad expenses if you buy from them. A few good bargains.

360 acre farm, 4½ miles from Crookston, Minn., (a city of 7,000 inhabitants), and 2½ miles from the State Experimental Farm. This is a photograph of the buildings as they are today: House is 16x24 1½ stories with an L 14x22, and a wood shed in connection 20 ft. square, all on a brick foundation. Barn 28x48, with a lean to 16x48, sheeted both inside and out. Two granaries, one 14x80, and the other 14x42. The buildings are all well painted and in very good repair, and has a fine artesian well. Every acre of this farm in under a high state of cultivation, and is well drained by a slight ravine running through the farm, merely sufficient for self drainage. The soil is a rich deep black loam with a clay sub-soil, and in every respect is considered to be one of the best farms in that vicinity. Our price on this farm is $35.00 per acre.

This is a **320** acre farm about 2½ miles south of the city, this farm is quite well improved, has a very good house of about seven rooms, 1½ stories, barn large enough for ten head of horses, also a good granary, pasture and an artesian well, also has a good well at the house, good grove around the building. This is a very choice piece of land for the price $32.50,

160 acres north-east of the city; this is all hay land, and located in a German settlement, the surrounding country is nearly all under cultivation; we consider this a good piece of land for an investment, this could all be put under the plow, if desired. Price $19.00 per acre.

HERE IS YOUR CHANCE!

For an "up-to-date" responsible dairyman, to rent, for term of years, a very desirable Ranch and 125 head milch cows, in one of the choicest dairy sections of California. No snow, nor yet excessive heat. Green grass the entire year. No winter feeding necessary. Freights reasonable. Apply to G. H. KELLOGG,
330 Pine St., San Francisco, Cali.

DAIRY FARM FOR SALE

Containing 214 ACRES of high, flat land in the town of Marcy, Oneida Co., N. Y., seven miles from Utica and one mile from Oriskany, in the Mohawk Valley. A large colonial brick house, four bay barn in excellent condition; reputed to be the best dairy farm in Oneida Co., will be sold at Public Auction to the highest bidder by the undersigned Referee appointed for that purpose by judgment of the Supreme Court in an action of partition, at the Court House, Utica, N. Y., June 25, 1903, at 12 m. Will keep from 80 to 100 head of cattle and near several lines of railroads. Well adapted for a fancy stock farm. Address inquiries to CLARENCE STETSON, Referee, or Lewis, Watkins & Titus, Plff's. Atty's, Utica, N. Y.

Gasoline Engines in Creameries.

(Paper read by E. E. Koch at the Wisconsin Buttermakers' Meeting.)

As Professor Farrington has asked me to write a paper on the use of gasoline engines in creameries I will attempt to do so, although I do not feel able to do it as it should be, and I hardly think you will enjoy another paper written by me after hearing this one, but experience is the best teacher as our worthy secretary will find from this experience.

I bought a six-horse-power Hart-Parr gasoline engine, September, 1902, and have used it since for creamery power, with a six horse-power boiler for heating purposes, but think an eight-horse-power engine would do my work more satisfactorily. The boiler is plenty big enough. I will say from what experience I have had with a gasoline engine that they are the power for creamery purposes. There are several reasons for saying so. They run with a little more even motion than steam, because, as a general thing, steam is up and down in a boiler, at least, that has been my experience, and when the steam goes up or down in the boiler it affects the motion of the engine, and an uneven motion will cause a separator to get out of balance soon and will not give as good results in separating as an even motion will.

Creameries can be run cheaper with gasoline engine and steam for heating purposes, than they can with steam for power. For example, will give you figures for four months in 1901 with steam for power and the same four months in 1902 with gasoline engine for power, and steam for heating purposes. September, October, November and December, 1901, I used 37 tons of coal at $3 83 per ton, $141.71; received during the four months, 382,105 pounds of milk. The cost of handling one thousand pounds was 37 cents. September, October, November and December, 1902, I used 304 gallons of gasoline at 11 1-10 cents per gallon, $33.77; 16 tons of coal at $3.92 per ton, $62.72; total, $96 49. Received during same months, 508,391 pounds of milk. The cost of handling one thousand pounds was 18 9-10 cents, a difference of 19 9-10 cents per thousand, but will say the old boiler I was using used more fuel than a new boiler would, so do not think these figures will apply to boilers which are in good shape.

I am satisfied there are creameries in Wisconsin which are using extra fuel enough, on account of inferior machinery, to pay interest on the money necessary to buy first-class machinery. I think there are other makes of gasoline engines probably just as good as the Hart-Parr, with one exception. It is an upright engine and does not rack the base as a horizontal engine will.

You can readily see that the concussion on a piston moving up and down will not rack the base as much as the concussion on a piston moving horizontally. A few miles from our factory there is a skimming station run by a 5½-horse-power horizontal engine. The engine was placed on a base very much like the one our engine is placed on, and their base is racked quite badly, while the base our engine rests on is as firm as ever. There is less work handling a gasoline engine; it uses less oil and is very clean.

I would say to those thinking of buying new power for their creameries, I would get an eight-horse-power gasoline engine and a six-horse-power boiler for a creamery running from seven to twelve thousand pounds of milk per day. In all cases get an engine with power enough to handle the machinery easily, and you will have no trouble with the engine. In getting an engine with plenty of power, the engine will last longer, use less gasoline and will not exhaust the battery so quickly as if you tax the engine heavily, which you will have to do, if you get one with just power enough to do your work. There are so many sparks in a battery. The oftener the engine ignites the more sparks it uses, and when the engine does its work easily it does not ignite so often, thus the battery will last longer.

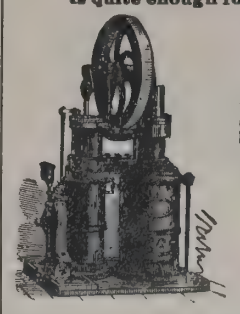
All gasoline engines from six to ten or twelve-horse-power, should use one gallon of gasoline every ten hours to run the engine. After that, it should use one gallon of gasoline for every horse-power used every ten hours. For example, a six-horse power engine if worked to its full capacity for ten hours, should use seven gallons of gasoline.

All gasoline engines for creamery purposes should have the cylinder enclosed, and so arranged that a six-inch stove pipe may be attached and piped out of the creamery, to carry the burnt gas out of the building, which passes through the cylinder. If an engine has but one ignitor attached to it, it should be a tube ignitor as it is surer than the spark ignitor, but I think both are necessary: if one should get out of order, the other could be used without delay. The spark ignitor is far the handier of the two. The engine can be started in a few seconds with the spark, while with the tube, it takes some minutes. There is a smell of burnt gasoline from the tube which does not come from the spark ignitor. If you have a gasoline engine and fire breaks out on the premises and you have plenty of hose, you can get the water where you most need it without delay.

There are three important things in handling a gasoline engine: First, plenty of gasoline, and supply tank; second, having both ignitors in running order; third, to avoid getting too much gasoline into the cylinder where gas explodes. This happens generally when the engine is hot, when being started after it has stopped recently. By getting too much gasoline in at once, it will not explode and will have to evaporate or be worked out by turning the engine some time with the ignitor attached and no gasoline allowed to flow in. This need not happen if operators are careful not to open valve which admits gasoline to engine, too much at first. An oil cooler is an improvement over the water cooler, as it does not need any attention winter or summer.

Some manufacturers will tell you the oil coolers are not a success, that they will not cool the cylinder properly in warm weather, because they do not make them. But experience has proven that they are a success.

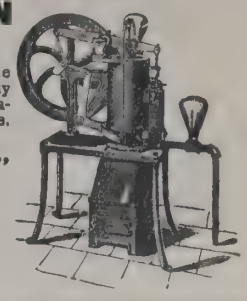
Danger in Pasturing Alfalfa.



Professor D. H. Otis of the Kansas Experiment Station says: There is probably no crop that appears more refreshing and inviting in the spring of the year than a good field of alfalfa. The plant starts early, makes rapid growth, and when dry feed becomes scarce or stale, there is a temptation to pasture it with various classes of stock. For horses, swine, or chickens, alfalfa undoubtedly furnishes the best pasture obtainable. For cattle, there are certain dangers attached to its use that should be carefully considered. The cow has four stomachs; the first, or paunch, is where the bulk of the food consumed is stored, ready to be ground in the process of chewing the cud. Under certain conditions, some feeds, green alfalfa being a notable example, while lying in the paunch will form gas, and when this gas is present in sufficient quantities it may cause the cow to bloat to such an extent as to cause death, unless the animal is punctured by making an opening into the paunch to allow the escape of the gas. No doubt if alfalfa could be used successfully as a cow pasture, it would mean greatly increased profit from both dairy and stock cattle. During the last two years the Kansas Station has been experimenting to see what could be done in the way of pasturing alfalfa. This work has covered both fall and spring seasons.

On September 26, 1901, nineteen common cows were given all the alfalfa hay they would eat, and in the afternoon pastured on alfalfa, which was in a fine succulent condition, as a result of the September rains. They were watched carefully and left in from an hour to an hour and a half. No bad results followed. The next morning they were again fed all the alfalfa hay they would eat, but after having had a taste of the green alfalfa they seemed to care very little for the hay. They were turned into alfalfa pasture at 7:20 a. m., and were taken out at 8:35 a. m. No sign of bloat was apparent. They were left in a dry lot, with access to alfalfa hay. At 1:20 p. m. one of the smaller cows was bloated. To give the matter a thorough test, the remainder of the herd was again turned on alfalfa pasture and remained there about fifty minutes, when one of the cows showed signs of bloating. Gas formed so rapidly that it was necessary to use the trocar and cannula. The paunch was so full of food that very little gas could be removed by the cannula. Four other cows were also bloated. Three were relieved by a gag, and one was finally relieved by the trocar and cannula, although complete relief did not occur until about 7.30 p. m.

The first of November we took ten calves, averaging about six months of age, and put them on alfalfa pasture, five with bits, and five without bits. These calves became accustomed to alfalfa



HALF ENOUGH WATER

Is quite enough for some people, but most people want water every day. If

RIDER or ERICSSON HOT AIR PUMPS

Are used you can have water every day in the year, and your cook or stable boy is the only engineer needed. 35,000 in daily use. Catalogue "B 5" on application to nearest store.

FARMER BRIGHTON, FAIRFIELD, IOWA.

gradually, the time being increased to fifteen minutes per day until they got all they would eat. This experiment was continued through the month of November, and we did not have a single case of bloat, with or without the bits.

We continued the experiment with the bits during the months of May and June, 1902, using cows instead of calves. Three cows were provided with bits and one without. These cows were first allowed to eat all the tame grass pasture that they could handle, after which they were turned on alfalfa for fifteen minutes. The next day they were given the same treatment, with the exception of increasing the time on the alfalfa to thirty minutes; the third day they were on one and one-half hours; the fourth three hours, and then all day, and a little later were allowed on all day and night. No case of bloat appeared for over a week. At this time the alfalfa was cut and soon after the cows were eating second growth. One morning soon after this, the cow without the bit bloated immediately after being watered; she was relieved of the gas by a gag, after which an alfalfa bit was placed in her mouth, when she was allowed to return to the alfalfa pasture. For a couple of days all went well, after which she bloated up six different times, and the last time had to be punctured. One of the other cows bloated three times and another four times. One of the cows went through the experiment without bloating at all. About the middle of June a fifth cow was added to the experiment with a bit. In less than ten days she had bloated twice.

Our experience indicates that it is unsafe to pasture alfalfa with cows, although some farmers have done it successfully, and we have done it successfully with the some individual animals. If a man wants to run the risk of pasturing alfalfa we believe the bits are a help, in that they prevent the cows from eating alfalfa as rapidly as they would without them. The bits might have some influence as a gag, although they appear to be rather small for this purpose and have a tendency to make the cow's mouth sore. Our experience indicates that the openings into the bore of the bit are of no particular value as they are stopped up with the green feed within five minutes after the cows commence eating. The straight bit seems to be better than the curved ones, as they are more easily cleaned. The cows did well while on alfalfa. They increased in the milk flow and not only did not need grain but would practically refuse to eat it, but they required so much watching, especially with the second growth of alfalfa, that we considered it too risky to keep them on it longer.

Infected Alfalfa Soil.

Dr. Cyril G. Hopkins, of the Illionis Experiment Station at Urbana, has just issued a circular (No. 76) entitled "Infected Alfalfa Soil," which is herewith reproduced: There has recently been some mention in the agricultural press of the difficulty of obtaining infected alfalfa soil for use in the inoculation of alfalfa fields. The Illinois Experiment Station is furnishing infected alfalfa soil to farmers in all sections of the State, as was announced last year in our bulletin No. 76, "Alfalfa on Illinois Soil," a second edition of which is now in press and will be sent to anyone free of charge upon application.

We furnish this soil in grain bags delivered to the railroad freight houses of Champaign or Urbana for 50 cents per 100 pounds to cover cost of collecting, drayage and bags. Remittance is best made by postoffice money order or Chicago bank draft. Personal checks are not accepted. Orders should be placed at least two or three weeks before the soil is wanted, as weather conditions may make it impossible to collect the soil promptly and get it in suitable condition for shipping. We advise using at least 100 lbs. of infected soil to the acre. Definite trials on large areas have shown that this amount is sufficient to produce a very satisfactory inoculation. The soil should be scattered over the field with some degree of uniformity; but it is not like seeding grain and it is not absolutely essential that every square yard in the field should receive its due portion of infected soil. Some care should be taken in spreading it over the higher places in the field but if places should be missed on sloping land or on lower lying lands, the bacteria will soon be carried over them by surface drainage waters; indeed, if all the water sheds in the field (that is, all ridges and high places) are well inoculated the entire field will ultimately become infected, the bacteria being carried by soil washing; but the infection is more rapid of course it the infected soil is spread over the entire field with some degree of uniformity when it is first applied.

If possible, the soil should be applied at about the time the alfalfa seed is sowed and then harrowed in with the seed; but it may be applied a month or two before sowing the alfalfa or at any time afterward, and it is not absolutely necessary that it be harrowed in, although that is advisable. If applied to a field where the alfalfa is already a year or two old, the infected soil may be mixed with the soil of the field by harrowing or disking (the disks being set straight so as not to cut off the alfalfa roots), preferably early in the spring or after a cutting has been made. Infected soil may be applied in any way to get it over the field, as by hand (throwing it from the wagon), with an end-gate seeder, if the soil is dry enough and sufficiently well pulverized, or in any other way which may be found convenient.

The results obtained during the past year (as will be shown in the second edition of Bulletin No. 76) fully confirm the results previously reported by this station concerning the importance and value of inoculation for alfalfa. The information which we now have, strongly indicates that if it is provided with the proper bacteria, alfalfa can be successfully grown on any soil where both corn and red clover are successful crops. Where there is difficulty in obtaining a good stand and luxuriant growth of red clover the soil is probably acid and should be treated with lime or ground limestone, and on soils which are deficient in phosphorous, an application of fine ground steamed bone meal or some other non-acidulated phosphorous fertilizer will be found profitable. Farm manure which is of such benefit to the corn crop has but very little value for alfalfa on most Illinois soils, when free from acidity and well provided with the alfalfa bacteria.

THE FARMER FAILS

In health just as does the city-man, and he fails commonly from the same cause, "stomach trouble." The farm is a wholesome place to live; the farmer's life is a healthy life; but no external advantages can overcome the effects of a diseased stomach. When the stomach and its allied organs of digestion and nutrition are diseased, the food eaten is imperfectly digested and assimilated, and the consequent loss of nurtition results in physical debility.

Dr. Pierce's Golden Medical Discovery cures diseases of the stomach and other organs of digestion and nutrition, and enables the perfect digestion and assimilation of food. It builds up the body with sound flesh and solid muscle.

"I used ten bottles of Dr. Pierce's Golden Medical Discovery and several vials of his 'Pleasant Pellets' a year ago this spring, and have had no trouble with indigestion since," writes Mr. W. T. Thompson, of Townsend, Broadwater Co., Montana. "Words fail to tell how thankful I am for the relief, as I had suffered so much and it seemed that the doctors could do me no good. I got down in weight to one hundred and twenty-five pounds, and was not able to work at all. Now I weigh nearly one hundred and sixty and can do a day's work on the farm. I have recommended your medicine to several, and shall always have a good word to say for Dr. Pierce and his medicines."

The sole motive for substitution is to permit the dealer to make the little more profit paid by the sale of less meritorious medicines. He gains; you lose, therefore accept no substitute for "Golden Medical Discovery."

KEYSTONE CALF FEEDER

Patented under No. 721,384. Used in about forty experiment stations. Mass. Ag'l College writes as follows: Mr. M. T. Phillips, Dear Sir:—I write to say that the Calf Feeder is giving excellent satisfaction. We have found it to be all we could ask for in a feeder. It is easily cleaned and appears to be durable. Yours truly, E. A. JONES, Supt.
Complete with extra nipple, $1.50, express prepaid. Circulars free.
M. T. PHILLIPS, POMEROY, PA.

Wide Fluctuation in Milk Yield.

(Continued from page 434)

feeding has anything whatever to do with the fluctuation in the yield of milk, but we do incline to the opinion that the cow is fed more than is really profitable and the probabilities are that quite a proportion of the present feed passes off undigested.

Testing Farm Separator Cream.

Prof. Farrington of the Wis. Experiment Station and Dairy School, gave a very thoughtful address at the Buttermakers' Convention, in Waukesea, part of which, was devoted to the above subject. Patrons as well as buttermakers should be deeply interested in this question for it is evident that farm separation is coming very rapidly. He said:

"The testing of cream is now a subject in which the buttermakers take a lively interest. They have to do a great deal more of it now than two years ago, and I think the universal experience of them all is, that cream testing is far more difficult than milk testing. The ordinary manipulations of the test are generally well understood, but there are a few points connected with the subject which I wish to mention. First, the sampling of cream for testing: this requires a great deal of care to have it done fairly. When cream haulers sample cream at different farms, a box of one-half pint bottles should be taken along and this box of samples ought to be iced in summer and kept from freezing in winter, just as carefully as the cream-carrying cans are protected. These half-pint bottles filled to the cover will furnish a good sized sample of each lot of cream, and when no preservative is used in them the buttermaker has a chance to inspect the condition of each lot of cream which was poured into the large cans. This will help him to locate any trouble he may be having with his butter. If these samples get sour and lumpy, there is some defect in the method of caring for them during transportation, but I think on the whole such a large sample as this, without using a preservative, until perhaps it arrives at the creamery, is the most satisfactory one to take. After the sample has been thoroughly mixed and tested, the cream, which is left, may be emptied into the cream vat.

When it comes to testing the cream, I presume that every buttermaker knows that the cream should be weighed and not measured into the test bottle. The scales made with agate bearings and knife edges are more easily kept in good condition for this purpose, than those having metal bearings, which will easily tarnish and rust. Another thing that will be of great aid in obtaining accurate readings of the cream fat, is to allow the test bottle to cool and the fat in the necks to solidify or crystallize after the last whirling in the centrifuge. This cooling helps to separate the water from the fat; this separation in many cases, has not been accomplished by the whirling alone. When remelted and warmed to about 120 degrees Fahrenheit the fat will be clear, oily, water-free and in the best condition possible for measuring.

"A new idea regarding the cream test bottle has been proposed and used somewhat in recent times. This is designed for the purpose of testing very rich cream. The commonly used cream bottles are graduated to measure 30 per cent fat when eighteen grams of cream are taken, but the new bottle is made with a longer neck and is whirled in a larger tester than those formerly made. My experience with these test bottles is rather limited, and I am consequently not able to discuss them, but I have always felt that so long a column of fat as would be separated from a 40 to 50 per cent cream was hard to measure accurately on account of the careful work needed in regulating the temperature of so much fat. The expansion and contraction of so long a column of fat affects the readings so much that it has always seemed to me to be safer to use less cream, say nine grams in a test bottle that will measure 30 per cent fat than to try to test 18 grams in a bottle that will measure 60 per cent fat. This use of the 30 per cent cream bottles will also make it possible to test all kinds of liquid dairy products in one tester or centrifuge."

Grit

Grit is a good thing in its place, but a bad thing in butter. Gritty salt—salt that's icy, insoluble, full of lime, chlorides and magnesium, is accountable for many exasperating difficulties of dairymen. It represents a loss of time, labor, money and patience, not always attributed to it. With DIAMOND CRYSTAL SALT—"*the Salt that's ALL Salt*"—your butter difficulties will disappear, and a gain in time, *money* and less labor result. Its dry, pure flakes dissolve quickly, imparting a rich flavor and keeping quality that find ready favor and highest market prices. "Just Salt" is a valuable booklet every dairyman should read. We send it free.

We feed "International Stock Food" every day to all of our WORLD CHAMPION STALLIONS, DAN PATCH 1:59 1/4 and DIRECTUM 2:05 1/4; to our YOUNG STALLIONS, BROOD MARES, COLTS, WORK HORSES, CATTLE and HOGS. "INTERNATIONAL STOCK FOOD" ☞3 FEEDS FOR ONE CENT☜ is Prepared from Roots, Herbs, Seeds, and Barks and Won the Highest Medal at Paris Exposition in 1900 as a High-Class vegetable, medicinal preparation to be fed to stock in small amounts as an addition to the regular feed. It is a Great Aid in Growing or Fattening stock because it increases the appetite and Aids Digestion and Assimilation so that each animal obtains more nutrition from the grain eaten. We positively guarantee that its use will make you extra money over the usual Plan of Growing and Fattening stock. "International Stock Food" can be fed in safety to Horses, Cattle, Sheep, Goats, Hogs, Colts, Calves, Lambs or Pigs. It is Absolutely Harmless even if taken into the Human System. You insist on eating medicinal ingredients with your Own feed at every meal. Salt is a stomach tonic and worm medicine, Pepper is a powerful stimulating tonic, Mustard is a remedy for dyspepsia, Vinegar is a diuretic. You eat these medicinal ingredients almost with every mouthful of your food, and it is proven that these medicines promote health and strength for people and improve their digestion. "International Stock Food" contains pure vegetable medicinal ingredients that are just as safe and as necessary an addition to the regular feed of your stock if you desire to keep them in the best possible condition. "International Stock Food" is endorsed by Every High-Class Farm Paper. It purifies the blood, stimulates and permanently strengthens the entire system so that disease is prevented or cured. "International Stock Food" is sold on a "Spot Cash Guarantee" by Fifty Thousand Dealers throughout the World. ☞Your Money will be Promptly Refunded in Any case of failure. It will make your Calves or Pigs grow Amazingly and has the largest sale in the World for keeping them healthy. ☞Beware of the many Cheap and Inferior Imitations! No Chemist can separate all the Different powdered Roots, Herbs, Barks and Seeds that we use. Any One claiming to do so Must be an Ignoramus or a Falsifier.

WHAT PEOPLE SAY ABOUT THIS BOOK.

INTERNATIONAL STOCK FOOD CO., EAU CLAIRE, WIS.

Dear Sirs:—I received your "International Stock Book" and was more than pleased with it. It is worth more than $10.00 to me. Very truly yours, RICHARD J. MORRISSEY.

INTERNATIONAL STOCK FOOD CO., ODESSA, MO.

Dear Sirs:—Your "International Stock Book" duly received, and it is the best thing of its class that I have ever seen. There is a volume of useful articles in it from start to finish. Respectfully, GEO. W. NULL.

A $3000.00 STOCK BOOK FREE

IT CONTAINS 183 LARGE ENGRAVINGS OF HORSES, CATTLE, SHEEP, POULTRY, ETC.

The Cover of this Book is a Beautiful Live Stock Picture ☞Printed in Six Brilliant Colors. Size of the book is 6½ by 9½ inches. It cost us $3000 to have our Artists and Engravers make these Engravings. It describes common Diseases, and tells how to treat them. It also gives Description, History and Illustrations of the Different Breeds of Horses, Cattle, Sheep, Goats, Hogs and Poultry. It contains Life Engravings of many very noted Animals, and also testimonials. The Editor Of This Paper Will Tell You That You Ought To Have This Stock Book In Your Library For Reference. ☞It Contains a Finely Illustrated Veterinary Department That Will Save You Hundreds of Dollars.

WE WILL MAIL IT TO YOU ABSOLUTELY FREE, ☞Postage Prepaid.

We Will Pay You $10.00 Cash if book is not as described. Write us at once, letter or postal card, and ANSWER THESE 2 QUESTIONS:

CLIMAX

Ensilage and Feed Cutters.

SOMETHING DIFFERENT. CLIMAX machines are not like others. Old ideas have been discarded, and the features are exclusive and original. Some of them are

STRAIGHT KNIVES. Easy to keep in order. Cheap to replace. Cut the material more evenly and do more of it.

ELEVATING. This is done with the same wheel as the cutting. Requires less power and NEVER clogs.

SMOOTH REVERSING GEAR. With this gear there are no cog wheels to break. The machine can be stopped or reversed in an instant without danger of breakage.

SIMPLICITY. No Feed Cutter made has so few wearing parts.

IT IS MOUNTED. Being specially built on trucks, it is just the right height for feeding No platform is required.

All these features are the result of long experience. They mean easier and quicker work and better results. Send for catalogue today.

THE COMPLETE MACHINE.

WARSAW-WILKINSON CO., WARSAW, N. Y.

A LONG WAY FROM HOME

Word just comes from far away Russia that the **Sharples Tubular Dairy Separators** received the highest award and gold medal at the **Moscow Exposition** where, after the most thorough trials, it was decided that the **Tubular** was entitled to first place. These victories, so common in America, are rapidly becoming a matter of course at foreign expositions wherever the **Tubulars** are exhibited. Notwithstanding the fact that foreign separators are better known in their own districts, dairy experts in all parts of the world must recognize the superiority of the Tubular in the following points:

Durability	**Lasting Qualities**
Simplicity	**No Complication**
Convenience	**New Improvements**
Efficiency	**Close Skimming**
Power	**Light Running**
Oiling	**Automatic Arrangement**
Cleanliness	**Simple Bowl**

The **Tubular** has so many good points that it takes a book to tell them all. We have one for that purpose and will send it free. Ask for our new catalogue, No. 144.

The Averill & Gregory Sale of Holsteins.

We are indebted to the Syracuse, (N. Y.) *Evening Herald* for the following report of the above sale which by the account will be seen to have been an extremely successful one. A picture of the great cow, Segis Inka, which sold for $1,600 will be found on page 374 of the DAIRYMAN and we thought so well of her from her photograph alone that we gave the picture the title of "A Study in Dairy Form." If her selling price is any indication of her actual value she is certainly worthy of the description given to her in the picture.

"Eccentricity" was the keynote of the bidding at the Averill & Gregory Holstein-Friesian sale yesterday afternoon, when the last of the famous herd went under the hammer. Purchasers paid big prices for animals which in no way ranked with some of the others that brought less. A. & G. Butter King, which was at the head of the A. & G. herd and accounted one of the best sires in the breed, went for $175, while A. R. Mills, of Portageville, paid $180 for A. & G. Maud Mooie Burk, a bull calf, not yet three months old.

The prices averaged well, however, and the sale was a distinct satisfaction to the proprietors of the farm and the Holstein breeders generally. One hundred and fifty-seven head of stock were sold for a total of $25,100, the average price being $159 81. Of these 157, one sold for $1,600, Segis Inka; one for $525, A. & G. Netherland Maud, one for $520, A. & G. Burke Segis Inka; one for $450, Netherland Maude Mooie, and one for $400, Mahomet Pauline DeKol.

Ten head were sold for between $300 and $400; 19 for between $200 and $300; 28 for between $150 and $200; 54 for between $100 and $150, and 41 below $100.

It is generally conceded that Dr. W. N. Landon, who bought the two highest priced cows at the sale got the best two animals. Doctor Landon, who is a comparatively new man in the breeding business, bid with rare judgment, waiting until the acknowledged experts began bidding on an animal and then, when the bidding had just about stopped, raising the price just sufficiently to shut everybody out.

There was a round of applause for him yesterday, when he bid and bought A. & G. Netherland Maud for $525 after a half dozen of the best judges had forced the price up to $500.

THE SALE OF SEGIS INKA.

Segis Inka acknowledged the applause which greeted her appearance Thursday in the auction ring with a loud-mouthed "moo." The auctioneer had scarcely offered her when E. J. Fargo of Lake Mills, Wis., bid $1,000, a price which was covered several times in less than a minute. The bidding was lively until $1,400 was reached, when all but Harvey A. Moyer, of this city, and F. P. Knowles of Worcester, Mass., dropped out. "Barney" Kelly forced the price slowly up at $25 jumps until it reached $1,500, when the enthusiam seemed to lag.

OFFERS FOR THR CALF.

The auctioneer pleaded and begged for twenty minutes or so, and it looked as if Segis Inka was to be bid off at that price, when Henry Stevens, the blind president of the Holstein-Friesian Association, arose and announced that he would give the services of his bull free, and pay $500 for the calf dropped by Segis Inka. He had scarcely dropped back into his seat when H. L. Bronson, of Cortland, announced that he would give the services of his bull free and $600 for the calf. The announcement was received with applause, and the bidding started in again until $1,550 was reached, when it lagged again.

Then W. A. Matteson, of Utica, started the pot boiling again with the statement that he would give the services of his bull free and $750 for Segis Inka's first calf and followed it up a few minutes later by saying that he would give the services of his bull free, and take the chances with the rest of buying the calf.

The price was forced up immediately until it reached $1,580, where it stuck. Mr. Knowles made the bid, and Mr. Moyer dropped out. It looked as if the celebrated cow was going to Massachusetts for all the efforts to get a higher price

(Continued on page 479.)

The woman of taste, means and refinement always wants the best soap to be had. She well knows that her beauty depends largely upon the healthy tint of the skin; and that this depends upon the purity of her soap. She likes pretty and scented toilet accessories, but she wants good soap for *use*. She has soaps, and soaps in fancy boxes, but she has a cake of Ivory Soap at her washbowl.

Making Ice Cream

The American public has a strongly developed appetite for ice cream in all its forms and it should be the duty of the dairymen to satisfy the appetite to as large a degree as possible whenever there is a market for the product. There is money for the dairyman in it if he puts a good article on the market, but the ice cream must be of good quality and well made. The following methods are given by Prof. Haywood the *National Stockman*:

CREAM MUST BE GOOD.

The chief requisite in the manufacture of good ice cream is good cream. By this is meant cream that contains from 23 to 25 per cent. of fat. With this quality of sound, sweet cream it is comparatively easy to make a first-class ice cream. If, however, this quality of cream is not available a fair quality of ice cream can be made from cream containing but 16 per cent. of fat by adding to the cream about 2 per cent of some gelatin filler.

THE PENNSYLVANIA DAIRY SCHOOL RULE.

The rule, if it can be called such, that has been followed by the dairy school for the past four years is as follows: For other than fruit flavors, two and one-half ounces of granulated sugar is weighed out to each pound of cream to be frozen. For chocolate flavor three-fourths of an ounce of Braun's chocolate paste is added to each pound of cream. The cream is put into the freezer which has previously been packed with a freezing mixture, the sugar and flavoring added, the cover put on and the freezer started; slowly at first to prevent churning, but rapidly as the cream begins to freeze. When crushed fruits are used for flavor the amount of sugar used need not to exceed two ounces to the pound of cream, as the fruit being preserved in a syrup already contains a large amount of sugar. One of the most popular fruit flavors is strawberry, an ounce of the crushed fruit and an ounce of the fruit juice usually giving the desired amount of flavor. When canned peaches are used for flavoring the flavor will be materially improved by adding the juice of a lemon to each can of peaches used.

EXTRACT FLAVORING.

In using extracts for flavoring it is usually necessary to flavor at least the first lots of cream made from each new lot of extract by taste, as it is difficult to get two shipments of extract of the same strength. Some ice cream makers claim that extract flavorings injure the grain or body of the ice cream. Whether this claim can be substantiated or not, it is almost certain that a more delicate flavor can be obtained from the vanilla bean for example, than from the extract of vanilla. Unless care is exercised in the selection and use of extracts they are likely to impart a characteristic disagreeable flavor to the ice cream. Where their use can be avoided they are not to be recommended.

BODY.

The body of the ice cream is influenced to a great extent by the richness of the cream used in its manufacture. Ice cream made from cream containing but from 16 to 20 per cent of fat will lack body or character, when put into the mouth it immediately melts and vanishes, which is disappointing to the lover of good ice cream. On the other hand when cream with from 23 to 25 per cent of fat is used the ice cream has a toughness that is regarded with favor by the ice cream connoisseur. Again, the richer ice cream is apparently not as cold as that made from poor cream and in consequence the consumer is not troubled with the pains in the roof of the mouth so often caused by eating ice cream made from poor cream or from eating water ice or sherbet.

Perhaps the rapidity of freezing has some influence upon the body of the ice cream. This in turn is influenced by the strength of the freezing mixture or the amount of salt that is added to the ice. One pound of coarse ice cream salt, to ten or twelve pounds of crushed ice gives a medium, quick,freezing mixture. The freezer should always be stopped as soon as the ice cream begins to roll up on the stirrer. If the freezing is carried too far the water in the cream freezes, the grain or body becomes granular and the cream is ruined.

THE YIELD OF ICE CREAM.

The yield of ice cream is governed perhaps by three factors. First, by the amount of air that can be incorporated into the freezing mass. Second, by the expansion of the milk albumen caused by whipping the cream during freezing, and, third, by the expansion of the cream serum during the freezing of the cream. The increase of ice cream over the unfrozen cream varies within very wide limits. Why it should vary and vary so widely is a question that a large number of experimental freezings has failed to answer satisfactorily. Ice cream makers frequently claim that they get an increase of one hundred per cent of ice cream over cream. While the writer has occasionally gotten an increase of 80 per cent the average has been approximately 60 per cent.

To obtain the greatest benefit of the increase of ice cream over cream it should be measured and disposed of as soon after feeezing as convenient. Ice cream served as soon as it has hardened after freezing, is very light and feathery and is preferred by many in this condition. If the ice cream is held in a packer for twenty-four hours a large part of the air that has been incorporated in it during freezing collects in the cream in such a way that, when the cream is stirred, as it has to be in repacking, it escapes and the bulk of the ice cream is reduced approximately ten per cent. As a consequence the cream has a more solid consistency and to some does not have the light, fluffy, lively attractiveness characteristic of freshly frozen cream.

PACKING ICE CREAM.

After the cream is frozen it is usually transferred to porcelain lined, iron packing cans packed in a freezing mixture in cedar tubes. From these the cream is distributed to the retail trade by means of small tin packing cans holding from one to four quarts. Ice cream should not be left in contact with metal for any considerable length of time, as the cream is liable to become tainted.

Care should be exercised to keep the cream in the large containers well packed to prevent the cream from becoming soft and to see that the freezing mixture in the retail packers is strong enough to keep the cream firm but not so strong that the cream will become so hard as to be unmanageable.

ICE CREAM BRICKS.

For the high class trade there is quite a demand for ice cream bricks containing from one to three flavors and two or more colors. These are made in a brick shaped tin mould, those having the double lid are much to be preferred. When more than one kind of cream is used in a single mould, care should be taken to make the different layers as even and as uniform as possible. Special care should also be taken to fill the mould as full as it will possibly hold, as moulds that are filled are not likely to be contaminated with salt in freezing. As soon as the moulds are full they are packed in a strong freezing mixture for an hour and a half or until the cream is frozen solid. They are then taken out, rinsed off with clean, cold water and both lids removed.

The thin blade of a knife is then run around the inside of the mould and the brick of ice cream pressed out upon a table. With a thin bladed knife the brick is cut into five or six pieces, each individual piece wrapped in paraffine paper, and put into a packer surrounded by a strong freezing mixture. Ice cream made into bricks frequently sells for from forty to seventy-five cents per quart.

A JERSEY MOTHER AND DAUGHTERS.
Property of Fred Stubley, Black Earth, Wis.

Working Under Hard Conditions.

Ed. Hoard's Dairyman:—Find enclosed money order for $1 to renew my allegiance to the Dairyman. I neglected to renew my subscription at its expiration and have been extremely busy and have been doing without the great Cow Apostle's advice, but for all that,we have been very successful and hadn't I ought to, I have been going to Cowlege, for over twenty years under the tutelage of Hoard, Henry, Buff Jersey, Goodrich, et al.

I am from Wisconsin, and last fall rented a farm in Brown Co., Minn. There were 28 cows in milk, including heifers and strippers and the monthly checks from creamery ranged from $50 to $60. We took charge of the business Oct. 1, and there was a marked improvement at once in the milk flow and the size of our checks till for December, it was over $106, brought about by proper care and handling. It must have been the care and regularity in milking; surely it was not the feed, for I must say it was the poorest feed I ever fed to cows, frosted corn fodder that had stood a month after being frosted before it was cut with corn binder.

It was planted late and was in all stages from silking to roasting ears when it was killed by frost early in Sept., so you can judge what the feed was like. I looked over the premises before renting, and barn and all buildings were in poor shape, especially the barn, it was awful filthy and bad. One part has no gutter behind the cows and by the removing of the droppings, the dirt has been removed to a depth of 18 to 24 inches.

The barn is set on posts and the cows passing in and out have carried out the dirt on each side and under the sill to a depth of 2 feet, and when we came here, that was full of slush composed of cow manure, water and dirt and the cow's udders, would drag in that filth and when they passed over the sill, the pressure on the udder was so great as to sometimes cause the milk to squirt from the teats;and say, wasn't it nice milking with udders and teats covered with such filth?

The other part of the barn was not quite so bad, but the owner, when he saw with what disgust I viewed the barn and their ways of doing, had many excuses to offer for having things thus. The main and only plausible reason was that he could not get help to do the work on the farm and fix the barn and many other things that needed doing just about as bad, and if I would rent the farm it would relieve him of the farm work and care of the cows and he would go right to work and fill in the barn and put in gutter, etc., and fix everything up in fine shape.

Well, when we took possession he didn't just have time to fix the barn and so it has gone. We did some temporary work, fixing so the cows could get in and out of barn without getting their udders covered with filth, but he hasn't done a thing yet, and I am thoroughly disgusted with the old prevaricator and procrastinator.

He was also to fence a hog pasture. I sowed the barley and rape for same, but that is all the good it did. It is a foot to 18 inches high, but the ten sows and their pigs remain shut up in a pen.

I will not wrangle with this man. I shall try to rent a farm with up-to-date buildings and equipment and let him have this all to himself. J. W. Vana.

Minn.

Care of Milk and Cream.

How Farmer Patrons of Creameries May Best Secure Milk Products of Extra High Quality.

W. A. Wilson, dairy superintendent, Regina, Assiniboia, Canada, in *Northwest Farmer*, reviews the methods of caring for milk and cream on the farm as follows:

During the present year indications thrroughout the west seen to warrent favorable prices for dairy produce, particularly for creamery butter. At present a ready market is available for the supply as soon as it is manufactured, and at a price from 2c to 4c a pound in advance of that for the corresponding period of the previous year. This, no doubt, will prove an inducement to have creameries commence operations earlier than usual, which will be greatly assisted by the pleasant weather of early spring and the splendid condition of the roads. In this respect the season will be a remarkable contrast to that of the early part of 1902, and a better season for co-operative dairying is almost evident. To obtain the maximum returns for the produce the attention of the dairymen, from the beginning of the season, should be centered on establishing a market on what they have to offer for sale by adopting methods in the care and handling of milk and cream on the farm which are beneficial, and whereby the raw material will not become contaminated.

CONTAMINATION OF MILK AFTER LEAVING THE UDDER OF THE COW.

Milk as it leaves the udder of a healthy cow is practically pure, free from germs and foreign matter. It may, however, become impure or tainted in various ways, as, for instance, in any of the following: 1. By mixture with it of particles of dirt, manure, bedding, hair, etc., during or after milking. 2. By absorbing strong odors as from manures, fertilizers, etc. 3. By introducing of bacteria, which may cause souring, or bitter, slimy, ropy, or so-called "bloody" milk.

Under the first condition milk is contaminated with filth of various kinds, in many cases through carelessness in the barns. There are likely to be particles of dust and dirt in the air and on the bodies of most cows, especially about the udder, which readily find access to the milk, chiefly during the milking period. The attempt to prevent this by attaching a strainer to the milk pail during milking is not advisable. Such strainers are cumbersome, they tend to spatter the milk and are disagreeable to use. The true method of preventing contamination of milk by such foreign matter as we are considering is to be sought in securing the right conditions in the stable, thoroughly cleansing the cow and by the employment of milkers clean in person and clothing who understand how the cow should be milked and who will do the work properly.

During the summer months, when the milking is done in the open air, the surrounding atmosphere should be pure, the milking done in a sheltered spot, which largely prevents the wind from blowing

dry dust into the milk, and the yard kept scrupulously clean. The whole body of the cow should be brushed and the udder and parts of the body adjacent to the udder should not only be brushed, but wiped with a damp cloth or sponge; dampening the hair just before milking will do much to prevent dust from the udder and parts adjacent falling into the pail. The dress and hands of the milker should be thoroughly clean, and milking always done with dry hands. If the hands could simply be moistened, the practice might allowable, but the practice of moistening the hands is apt to degenerate into the habit of making them wet, so wet that there is a drip from the hands into the pail, which means filth and which cannot be too strongly condemned.

Owing to the marvelous rapidity with which it absorbs odors while cooling, the milk should be removed from the stable as soon as it is drawn. While the aim should be to keep the stable free from odors this result can seldom be so perfectly attained as to make it desirable that the milk should stand in the stable, or in an atmosphere polluted with stable odors, or such as are too often manifest near the milking pen.

The use of a fine cloth strainer is desirable, but it should be remembered that the mere straining of milk does not undo the evil of filthy milking, and also, that the carelessness in washing and sterilizing the strainer cloth may lead to serious trouble in contaminating the fresh milk. The cloth should be rinsed and thoroughly washed in tepid water and as a last operation sterilized in boiling water.

CONTAMINATION BY MEANS OF BACTERIA.

Probably the most common form of contamination of milk comes under this head. Milk as it is secreted by a healthy cow is believed to be sterile, that is, it contains no germs. So far as it is known it is not possible for bacteria of any kind to pass through the digestive organs and the blood vessels, and appear in the milk. In the end of the teat of the cow, however, which is usually moist and its temperature favorable to the multiplication of germs, the organisms are invariably found, and it is because of this probability that it is advisable to discard the first few streams of milk drawn from the cow, which wash out and hold the germs lodged at the end of the teat. It is practically impossible to milk a cow under such conditions that no bacteria will find their way into the milk.

They are to be found almost everywhere and the air and fine particles of dust contain many of those minute organisms. They find a fertile and congenial medium for growth and multiplication in the warm milk as it is drawn from the cow, and while absolute freedom from bacteria is an impossibility, the number can be kept relatively low by observing the conditions of cleanliness, alluded to previously, and by immediately cooling the milk to at least 60° F., and retaining it at that temperature until delivered to the creamery. At a moderately high temperature, or from 70° to 100° F., bacteria multiply with marvelous rapidity, while below 60° F., their growth is very materially checked, and the milk or cream will keep free from taint for a considerably longer period. Milk pails and dairy utensils of various kinds are often the source from which bacteria find their way into the milk. Having been used to hold milk in which bacteria have multiplied and then being imperfectly cleansed, they abundantly seed the new milk put into them with germs of various kinds. All dairy utensils should be smooth, especially in the interior, and the seams of the tin pails should be perfectly filled with solder. Wooden pails should never be used. Every dairy should have a plentiful supply of hot and cold water, and, if possible, steam. All tinware used in handling milk or cream should be first rinsed in warm water, then thoroughly washed in hot water and strong soap or washing soda, then rinsed and finally scalded or steamed for several minutes. Simply turning live steam into a can or pail is not all that is necessary. The steam needs time to reach every crevice and corner. Cloths and sponges should be used as little as possible in washing dairy utensils; brushes are preferable.

From the time the milk is drawn from the cow until the butter is manufactured, much trouble will be avoided if cleanliness is observed in every detail from start to finish, and the milk immediately cooled and kept below 60 deg. F., where the surrounding air is free from odors and dust, and where perfect ventilation is easily attainable. It will also result in a superior finished product.

Drought and Catch Crops.

ED. HOARD'S DAIRYMAN:—The severe drought in Maine was broken on June 8th, 9th, and the week was marked by cool, cloudy weather with more rain later toward the end.

The hay crop may grow up in some localities so as to be worth harvesting as a rather late crop. Crops for a quick growth of forage are in order. Nowhere can anything be found which is likely to equal Indian corn, if sown in rows, rather thick, and cultivated during its early growth. We would not hesitate to plow quite late for this crop—all through June, in fact. Turn the furrow slice completely over and cultivate nearly or quite half way through it, without bringing the turf to the surface. This can easily be done with roller, or drag and slant-toothed harrows, such as Thomas Smoothing or cut away. Do not use a spring tooth which lifts and digs.

Many Maine farmers know the value of flat turnips sown broadcast. These can be used for pigs, young cattle and dry cows. It is not a time to spend much effort on new, untried things, and we would pin our faith on rather large areas of these stand-bys and go right at it and put in a good, large area and then add a little to one or both, later. Would advise trying sorghum if it did not need so careful hand work the first of its growth.

This is a good time to make a beginning to stem the leak of money from the farm in the high-priced by-products—bran, etc. We would begin with not less than an acre and from that to ten acres of good land put into alfalfa. Plow the ground at your leisure soon after putting in the corn and turnips. Plow and cultivate in the same careful way. You may be able to leave the land a few days if cultivated as fast as plowed. Then go over it a few times more to insure a good moist seed bed. Then sow 10 to 18 pounds of fresh alfalfa seed per acre. On good, rich land worked to a fine seed bed the less amount of good seed will produce a good stand of plants. On poorer land especially if not fine and reduced to good seeding surface, 18 or 20 pounds is none too much, and we would hesitate to insure a crop of any kind on such preparation.

The alfalfa should be sown in August. We would try to sow it early in that month, and if conditions were favorable would be prepared to run the mower over it in September. No pasturing should be allowed unless, if not cut, and it were pretty tall in October and the ground firm, we might turn sheep and calves over it, but we we would not allow them to stop long, or to camp on it. Last year a seeding of nine acres under the writer's direction on the Laramie Plains with one late irrigation, succeeded well enough to yield a pretty fair cutting. It was sown in June. In North Carolina, August is the best month to sow alfalfa as demonstrated by Mr. Brandly, farmer for the Biltmore estate. This mountain climate somewhat approaches that of the northeastern states only shorter and milder winters, but more trying conditions in other respects.

Alfalfa is being grown successfully in New York state. Originally introduced there about a hundred years ago it was neglected, to be again introduced about twenty or more years ago at the State Experiment Station. Hay was made there on which a digestion experiment was made, and this, combined with one made in Colorado, showed digestible nutrients practically equal pound for pound, to wheat bran. From this second introduction the spread of alfalfa growing has been considerable. One authority, a couple of years ago, claimed at least 50,000 acres in and near one county in central New York. (See Coburn's Alfalfa.)

Writers have shown the hardiness of alfalfa. It resists severe cold. Drought harms it about the least of cultivated crops. This crop does not bear flooding and growers will do well to put it on land which does not overflow, or on which water does not collect and stand. Though such land when well underdrained, may produce good crops of alfalfa.

Good articles have recently appeared in HOARD'S DAIRYMAN on alfalfa, notably on pages 374 and 403.

Lastly, in regard to the permanence of a seeding of alfalfa: Once you get a good stand it should remain good, if not abused, for at least ten years.

What do we mean by, "if not abused?" Why, if not pastured with heavy animals; if all animals are kept off when the land is wet; if the cuttings are so timed that no seed is formed; if some care is taken to replace some of the plant food "grown off" from the land, by top-dressings put back on the alfalfa field. These top dressings may be of good stable manure put on with a manure spreader, or even, of only muck; or they may be of ashes, unleached hardwood, or leached, but proportioned to the amount of plant food contained in the substance spread out on the alfalfa. FRANK E. EMERY.

A Letter From H. E. Cook.

ED. HOARD'S DAIRYMAN:—I notice on page 415 of recent issue, you touch me up on the old rigid stanchion.

I am sorry you guessed and then argued from a presumption—of course for many years we did use them but of recent years the swing stanchion hung with chain, has taken their place. Now I don't think these conditions are ideal. The only all-around perfect place for a cow is to run loose in a box stall, but that makes for so large a breathing space that the animal can not warm it and so there seems but one way out and that to be secured some way upon a platform and space minimized. A mistake that we made, but have changed many of the platforms and shall, before winter, change the balance, was in using a platform too narrow, that brought the udder against the corner of the gutter, and another, of having insufficient width of stall. For cows weighing 1,050 to 1,150 pounds, 5 feet in length of platform and 4 feet for width is about right. This size, with the swing stanchions is very satisfactory.

There is, however, with me yet, some loss. It comes as often in the summer as in the winter. It comes in dry, warm weather, as well as in cold, damp weather and so far as I know it affects very many fairly good cow keepers in the same way.

I know I do not always have the most careful milkers. I like to have things "go," and so the men around are usually those who are active, hustling fellows, and such men are hustling milkers and injury comes from that source, sometimes another trouble. I want the cows to work to their limit, just as I do myself, and so here comes an organic difficulty of working the cows very hard, and when this is done, that part most severely taxed gives out first. I do not say this is always the best way. And so we might go on indefinitely; but enough. I know it does a fellow good occasionally to confess to his faults,—"open confession," etc.

I can see the mistakes of the past and and of the present, and these I am trying to avoid, but new conditions, new problems are constantly arising that keep me guessing. I commenced working over cheese vats and churns twenty-seven years ago, and I thought after a couple of years that the course would be smooth. I am yearly confronted with perplexities as hard to solve as they were then. I suppose, Mr. Editor, when these troubles all cease, the millenium will have dawned; and furthermore, when the time comes that I am unable to make

How To Cheapen The Cost Of Milk Production.

Mr. E. K. Slater, one of the inspectors on the staff of the Dairy and Food Commissioner of Minnesota, contributes some very excellent advice on this subject to the *Dairy Record.* It may be said with great truth that Mr. Slater contributes nothing new on this subject, but he reiterates old truths in a new and convincing way, and if every cow keeper in the land would take heed to what he says, there would be much less complaint that dairying don't pay. Note what our friend from Marshfield says in his communication, asking how to handle a bull, in our inquiry department. He reports that his cows pay him a net profit of over $100 each per year. This means, in the first place, that he has the proper style of machinery, to wit, cows, and then he takes proper care of this machinery. He does not say, but the presumption is, that he disposes of his milk to town customers and probably in estimating his profits per cow, does not deduct the cost of delivering this milk, but if we make the most liberal estimate on this score, there will remain at least $50 net profit per cow, after all expenses are paid.

Mr. Slater writes as follows:—We may improve the facilities for turning out the best buttermakers in the country. We may build the finest creameries that money can pay for. And we may encourage the output of fancy butter until the day of the millenium; but we will not be directly aiding or strengthening those forces which are responsible for future dairy progress.

The primary problem in dairy progress is the cow and her care.

Not many years ago gentle, unassuming "old Brin" was responsible for everything going into the make-up of the butter.

Now the facilities for handling milk and cream have been greatly improved and they, to a large extent, control the flavor of the finished product. The cow, however, is still the source of supply of raw material.

It is the duty of the creamery, with its improved machinery and high priced butter maker, to convert the raw material into butter at the minimum expense, but the cow precedes the factory.

It is the opinion of the writer that the subject of cost of milk production is the most vital one confronting the dairy industry of the country today.

If dairying is to continue in the ascendency the dairy farmer must realize that milk must be produced at a minimum cost or the profits accruing from the business cannot be satisfactory.

The dairyman who produces a pound of butter on his farm at a cost of 10 or 12 cents receives just as much for his butter on the market as the dairyman who produces butter at a cost of 18 or 20 cents per pound.

The profit depends on the difference between the cost of production and price received for the butter.

Among our creameries the price paid for butter fat will average about the same during the year, while the cost of producing a pound of butter fat on the farm will vary from 7 to 8 to as high as 25 cents per pound.

Is it not evident, therefore, that the cost of production is the most important item to be taken into consideration on the dairy farm?

In order to produce milk at a low cost it is necessary to have the proper style of machinery to manufacture that milk. The beef cow is not "cut out" for producing milk at a low cost, and the sooner the dairymen of the country realize this fact, the sooner they will solve the problem of cost of milk production.

Alfalfa in Ohio, Cutting and Curing.

ED. HOARD'S DAIRYMAN:—Yes, we can grow alfalfa in this climate grandly and, after we learn its habits, get a stand, generally. And when well cured it is one of the best of feeds, equaled only in productiveness by king corn, and it possesses certain qualities, both in feeding and growing, that makes it a companion and not a competitor to corn.

We can grow it in the corn belt probably better than elsewhere in the United States. The moist air gives it great vigor, but I am "up against" that one phase "properly cured." Experience teaches me to cut it whenever it begins to turn yellow near the ground and drop the bottom leaves. Don't look for bloom if it will cut a swath. You can rake and cut it at once, but how can you cure it?

Last year was an exception, but this year all was ready May 16th, and although the crop was short we cut down as much in the evening as we thought we could take up Monday afternoon, and do some more cutting. This is our system, Sundays excepted: cut one afternoon or evening before it begins to get damp. The next day throw this together in a loose, wide windrow with a side delivery rake. This is to keep the dew from falling on the cured hay. Next day as soon as the dew is thoroughly dried off and the leaves show the least tendency to crumble, turn it over with the side delivery rake. This leaves it in a loose, continuous windrow and ready for the loader, which we like to start soon after dinner, but all depends on the weather.

This year we had the weather our way and the most of our hay was housed to our notion. True, it was heavy and compact, but it was short and so leafy. It surely was the ideal. It was taken to the barn and unloaded by hand so as to be sure and have it spread evenly. I expected it to cure brown and get very warm, but just as we finished the rain commenced, and it has rained for three weeks. That hay settled and settled and got hot. Oh, my! You could no more bear your hand down in it than in boiling water.

I got scared and dug down to find it as brown as mahogany; no mold or decay, but wet and hot. I would have thrown it out if I had not taken sick, but we used the last of our corn silage a few days ago and we had begun using this alfalfa a week before to get the cows used to it. They ate it well and do well upon it, with good blue grass pasture. It is cooling off now, but it is silage, not hay. It is damp and dark; yet no mold only on top and the sides.

I am sure that clover and alfalfa can be cured to a fine quality of hay by stacking or mowing when just right. I do not mean dry, but containing no external moisture. I have seen enough to convince me of this in my own barn; and unless there is some way to cure it besides in the cock or windrow, alfalfa will be a failure on most farms in the corn belt. True, I can silo it, I have no doubt, but I want my silos for corn and the alfalfa for dry feed besides.

Many farmers have no silo. My second crop is most ready. I had intended stacking it, only wilted, believing it would cure out dry and only have 10 or 12 inches of mold around the outside, but if it cures wet when so nearly dry, will it cure dry even though I stack it to give it equal ventilation, and no obstruction in settling.

The rains will not penetrate it to harm it if the internal curing process is all right. I surely saw many accounts years ago of experiments along this line. These stacks were cabled down, but that is not necessary; it will settle tight. I feel it too expensive for me to try this at my own risk and kindly ask for whatever knowledge there is to be had on it, and will say if the knowledge is meager it surely would be a fit subject for our stations to demonstrate for us as there are thousands of farmers sowing alfalfa this spring.

P. CLAWSON.

Butler Co., Ohio.

Performance a Test of Merit.

We find the following very sensible comments and conclusions in the columns of our esteemed contemporary, The *Wisconsin Agriculturist.*

Performance is something that must not be lost sight of by the practical dairyman in grading up his herd. Sometimes the fancy points of the breed he is using for the grading up, and sometimes a little thing like color, will influence a breeder much more than it ought.

One of the best grade herds an *Agriculturist* representative who travels about the state remembers having seen, were grade Jerseys, and the wise owner made production the standard by which the cows eligible to a place in the herd were judged. The butter record was set at 350 pounds and every cow's production was judged by the Babcock test.

But the point we were getting at is that though this herd was far above the average of many pure bred herds, some Jersey men would have objected to many of the individuals because they were so dark in color. We do not think that this discrimination is as marked as it was some time since and it is time that it be done away with in herds where production is the measure of value. Some men would keep a cow in a grade herd because she was a nice type, and pretty, even if she did not make money enough to pay for her feed, but the practical dairyman must not do it.

Destroying Insects in Stored Grain.

ED. HOARD'S DAIRYMAN:—Your subscriber who inquires on page 437 as to how to destroy weevils in ground feed can get the desired information in Farmers' Bulletins Nos. 45 and 145 which treat respectively on insects injurious to stored grain and the use of carbon bisulphid as an insecticide. These bulletins he can obtain free by writing to the Secretary of Agriculture, Washington, D. C.

BRAIN BUILDING

How to Feed Nervous Cases.

Hysteria sometimes leads to insanity and should be treated through feeding the brain and nerves upon scientifically selected food that restores the lost delicate gray matter. Proof of the power of the brain food Grape-Nuts is remarkably strong.

"About 8 years ago when working very hard as a court stenographer I collapsed physically and then nervously and was taken to the State Hospital for the insane at Lincoln, Neb., a raving maniac.

"They had to keep me in a strait-Jacket and I was kept in the worst ward for three months. I was finally dismissed in the following May but did no brain work for years until last fall when I was persuaded to take the testimony in two cases. One of these was a murder case and the strain upon my nervous system was so great that I would have broken down again except for the strength I had built up by the use of Grape-Nuts. When I began to feel the pressure of the work on my brain and nerves I simply increased the amount of Grape-Nuts and used the food more regularly.

"I now feel like my old self again and am healthy and happy. I am sure that if I had known of Grape-Nuts when I had my trouble 8 years ago I would never have collapsed and this dark spot in my life would never have happened. Grape-Nuts' power as a brain food is simply wonderful and I do not believe any stomach is so weak that it cannot digest this wonderful food. I feel a delicacy about having my name appear in public but if you think it would help any poor sufferer you can use it." Name given by Postum Co., Battle Creek, Mich.

There are desserts and desserts. The delicious health-giving kind are told about in the little recipe book found in each package of Grape-Nuts.

How's This for a Record?

Emporia, Kans., Jan. 2nd, 1903.

Empire Cream Separator Co., Bloomfield, N. J.

Dear Sirs: Have used one of your **Empire** Cream Separators for the past eight years, during which time I have been milking at all times from twelve to fifteen cows. The cost for repairs in the eight years has been only seventy-five cents. I have had experience with other separators but consider the **Empire** superior to any other, as it never caused me any bother. It is easy to clean and has proven very durable. It does good work at all times. L. H. VAHSHOLTZ, Rural Route No. 4.

The Empire Cream Separator turns more easily, is more easily cleaned, does better work, and costs less for repairs than any other, because it is the **simplest separator made.** Don't buy a separator until you have investigated the merits of the Empire.

WILL IT PAY YOU TO TAKE HOARD'S DAIRYMAN?

W. H. Jenkins took a census in 1901 of 50 farmers who were patrons of the creamery in Montrose, Pa. Twenty-five of themread dairy papers; twenty-five did not. The twenty-five who did read dairy papers averaged $50.23 per cow for the year. The twenty-five who did not read averaged $32.95. Here is a difference of $17.28 per cow. Did it pay the twenty-five to read? Did it pay the other twenty-five not to read? That's not all. Those who did read averaged a profit over cost of food of $15.06 per cow. Those who did not read averaged a profit of 66 cents. Is not that dairy farmer standing greatly in his own ight who will not pay 2 cents a week for Hoard's Dairyman? These are hard facts worth thinking over.

How long a sowing of alfalfa will last is unknown, so many things depend on climatic conditions, but from Texas comes the report of a patch of alfalfa that was sown in 1868, and is consequently now about 35 years old.

R. T. D., OF Vermont asks John Gould some questions in another column, and in the course of his communication makes the not uncommon remark, that manure improves in quality with age, if stored in a manure cellar. We would like to have him give some reason for this statement, and our columns are open for discussion of this important topic.

ONE of the German agriculturists now touring the country, criticised the placing of a hand separator in the middle of the dairy barn and stated that the German law would forbid the placing of a separator in such a situation. Why? Because of the liability of the cream absorbing barn odors, with consequent lowering of the quality of the butter. They evidently believe in preventing the introduction of off flavors in the milk instead of relying on the ability of the butter maker to get them out afterwards.

THE *Drover's Journal* of Chicago is calling loudly for a thorough awakening on the part of the dairymen of Illinois. It declares the state is running clear behind in everything pertaining to dairy progress. Young men are sent to the dairy schools of other states because they have none worthy of the name at home. The *Journal* demands that a radical change be made in the creamery management of the state. It points to Minnesota for an example of what a first-class dairy state should be. Minnesota grants a liberal appropriation for special dairy education and keeps up a first-class dairy commission and a number of inspectors, who travel the state constantly.

What the *Journal* says about the backward condition of the Illinois dairymen is true, every word of it. Several of the leading dairymen of that State have repeatedly spoken to us lamenting most decidedly the lack of true dairy spirit in the state. Illinois is a very wealthy state and it is to be regretted that her University has not taken the lead more than it has in promoting dairy education and progress in that state. The interest suffers in many ways because of the state of indifference which prevails.

We are quite content to let Mr. Grote have his say, in another place in this issue, on the question whether concentrated feed stuffs can be used with profit in the daily ration of the milch cow, with no other comment thereon than the one suggestion, that farm-grown grain crops are fully as "concentrated" as the general run of the so-called by-products. Therefore the "facts" for which he makes such insistent demand apply with as much pertinence to "rations which can be raised on the farm" as to rations made up in part from purchased products. The really important question is whether the farmer can or cannot sell farm-grown feeds and purchase other feed-stuffs at a profit.

For an example, take oats and bran. When oats can be sold for 32 cents per bushel, which is $20 per ton, what can the dairy farmer afford to pay for bran? Disregarding for the present the difference in manurial value which can be realized after feeding a ton of each and amounts to $2.14, we have the fact, shown by chemical analysis and digestion experiments, that bran contains an average of 58 per cent digestible nutrients and oats 66 per cent, or 14 per cent more than bran, and bran 12½ per cent (one-eight) less than oats.

Notwithstanding feeding trials have shown only 10 per cent in favor of oats, let us give them the full benefit of their theoretical value, and, making an allowance of $3 for cost of hauling back and forth, we will have $14.50 as the amount the farmer could afford to pay for one ton of bran when oats sell at the barn for 32 cents per bushel. The $2.14 additional manurial value of the bran is the clear profit in the transaction.

Our gifted contemporary the *Jersey Bulletin*, as might have been expected, "chortles" somewhat exuberantly over the change in the rules of the Holstein-Friesian Association, in regard to estimating the practicable yield of butter from a test showing the amount of butter fat, apparantly unmindful of the fact that it "lives and moves and has its being" in a very frail glass tenement, so far as "records" are concerned.

For example, one of the many skits in its issue of June 17th, reads as follows:

Jersey breeders are wholly unable to symphathize with the Holstein breeders if those Advanced Registry records are placed where impossible things ought to be. They can not imagine the result if all the records of Jersey cows should be nullified at "one fell swoop." Just imagine, if you can, the situation in Jersey breeding circles if our records had all been made by guess work, and we found our estimates all wrong, and based on an impossibility. But there is no chance for such blunders when you churn and weigh the butter, as Jersey breeders were wise enough to do.

The great reliability and freedom from "blunders when you churn and weigh the butter," so boastingly advanced by the *Bulletin*, receives a solar-plexus blow in an adjoining column of the same paper and in charity to the weakness, inseparable from a breed organ, we copy, but forebear to comment.

The Chemist of the Ontario Agricultural College, in the twenty-eighth annual report of that institution, makes note of a sample of butter received by him, that upon analysis showed the abnormal amount of 53 per cent water. He says:

"The tester was put to the bottom of the crock and when withdrawn showed no signs of the excessive amount of water, and when turned out, the butter left the crock clean and dry, showing no moisture apparently."

No doubt it had been treated with one of the nostrums which make it possible to retail water at 20 to 30 cents per pound: or was the analytical operation at fault?

A GOOD THOUGHT ON EDUCATION.

The other day we heard a farmer's son bemoaning the fact that he had been given nothing better than a good high school education. We did not exactly like the spirit in which he spoke. There was more of the ring of discontent than of manly pluck in his voice. Then we thought of the hundreds of good farmers we know, who were given nothing better than a country district school in their boyhood days, and along with it the solid, hard work training of the farm. Plenty of men among this number have amassed a good fortune, have fine homes and every comfort about them, with a well stocked library supplied with the best books, magazines and news papers of the day. *They have educated themselves every day in the year since they went to school.* They are well educated men too. A college cannot give a man an education, and a farm cannot prevent one either. It all depends on the boy and man, wherever he is.

Here is what Elbert Hubbard says, and it is right to the point:

"Education is a matter of desire—no man was ever better educated than he wished to be. If you desire education you will find opportunity for improvement on every hand. Providence is on your side, and time and chance will join hands to assist you—not always to give you the exact education you had in mind, but you will get something just as good. That is Nature's way—you choose one thing and you are given another; but if you never desire anything then you get nothing, Nature helps every man to become what he wants to become. The energy you put forth in securing a college degree, will secure a prize of relative value somewhere else. The man who is diligent at college will be diligent in business, serving the Lord; he is by nature, and will be diligent anywhere. The boy who is a loafer at home will be a loafer at college."

So the DAIRYMAN says, let no man lament his hindrances, for if he is the right kind of a man hindrances will help.

"I CAN'T SEE."

Not long since we were telling a farmer neighbor of the results of our experiments with alfalfa, especially as to what we had learned concerning its more than double value over clover as a milk producing food, and we added as a further consideration that the past summer our alfalfa fields had grown three heavy cuttings, or over 7 tons to the acre. To this he replied: "That all may be true, but *I can't see* that alfalfa is worth any more than clover to feed cows."

Another farmer came to us recently and traded a nice grade Jersey heifer calf three weeks old for a half grade Guernsey bull calf of the same age. He proposed to raise this bull calf to use at the head of his herd to improve the quality of the resulting heifers. He really said he wished to "grade up" his cows. When asked why he did not use a thoroughbred Guernsey, and so have pure a fountain of dairy qualities to draw from, he said: "I don't see why a full blood is any better than a grade for that purpose."

Another neighbor stood beside the fence one day and watched our teams as they were going with the disc harrow, over a field that had grown silo corn the past summer. "What are you doing that for?" he asked. "We are going to sow that field to rye as a cover crop for the winter, and to plow under next spring," was the answer. "Why do you do that?" "Because we have not manure enough to go over it as we ought and the land needs humus. It takes about a bushel of rye and the labor, and it is a paying thing to do." He turned away with a look which said: "That's some of Hoard's book farming" and then he said, "*I can't see* that it will pay to do all that."

Here were three men and they represent thousands of like make up who "can't see." There is a fearful amount of that "can't see" condition among the farmers of the land. They don't see because they take no pains to see, or maybe they think the truth will come to them and force them to see it. Mingled with all this exists an indifference, a sort of don't-care-whether-I-see-or-not. With such farmers there is no real hunger or thirst for any better knowledge than they now possess, a supreme contentment they have in the poor, impracticable methods they daily pursue. No man can make any progress or the best profit as long as he keeps up the cry, "I can't see."

Every man is responsible as to whether he sees or don't see. He must make an effort to see. He must try and look into things. An old negro preacher once said to his congregation, "If de Lord ebber gets you into Hebben, he done got to tie yo' laigs an' frow yo' dere by main force."

Some farmers we know of are evidently waiting for some such interposition of power to make them see. One farmer in this county made serious objection to his son attending the Short Course the coming winter at the Wisconsin Agricultural College. He said, "it is all blamed nonsense to throw away money for what you get there."

He was blind and wanted his son to be blind, "like unto himself."

No other calling in American society that we know of, contains so many men who "can't see," and who really make no effort to see. Fortunately for the honor and progress of Agriculture, there is a constantly increasing number who propose to see whatever truth exists that makes for their profit in farming. On them will depend the future of the American farm.

A LETTER FROM A READING, THINKING, HIRED MAN.

There is nothing better on a dairy farm than a reading, thinking, hired man. Such a man, if he is industrious and faithful, is sure to command the highest wages and hold his place against all comers. It gives us great pleasure to publish the following letter from such a man:

ED. HOARD'S DAIRYMAN:—As I am very much pleased with your paper I enclose one dollar for you to continue it another year. I do not have very good luck with the coin cards you sent me. The farmers claim that book farming costs too much, but there is enough in HOARD'S DAIRYMAN every week to interest me, even though I do not keep any cows. I think it likely, however, that I will commence farming before long. I am working by the month, and I have thought some of going west, even to the state of Washington. Would you advise a young man to go there that desires to engage in farming? I would rather farm than engage in any other work.

Wishing you the best success with your paper, I am very truly,

Rome, N. Y. JOHN AEGERTER.

We have no fears of Mr. Aegerter making a success of himself on the farm whether he goes to Washington or any other good dairy state. He is starting right and that is a good deal.

When a young man proposes to first set his mind and understanding right, all of his subsequent labor will follow in right lines. The state of Washington presents some good attractions in the way of dairy farming. So does the state of New York. We have many times thought that the largest, natural advantages for successful dairy farming are to be found in the east. Good farms, with good barns and stables, good society

and schools and the best of markets, with land very cheap, can be found in New York.

We have in mind now a couple of young men, Germans, who bought a dairy farm of 160 acres three years ago in the town of Stockbridge, Madison Co., New York, for $3,600. Thirty years ago that farm would have sold for $100 an acre. These young men are thoroughgoing dairy farmers, and they are making handsome money. With modern, intelligent methods those eastern farms can be quickly brought back to their former productiveness.

It is the man, his brain, skill and energy that tells. Just in proportion as these essential qualities fade out in any community, does the price of land decline, and sometimes that is the very place for a bright, plucky young man to take hold. He can get cheap land and large outside advantages.

We can hardly understand why the farmers about Mr. Aegerter should claim "book farming costs too much." Certainly they have never tried it.

The other kind of farming has cost the state of New York fifteen hundred millions of dollars in 30 years, in the decline of values in her farm lands. Her anti-book farmers have nothing to boast of in the way of economy.

SOME THINGS ABOUT THE BABCOCK TEST FOR THE FARMER TO CONSIDER.

The Continental Creamery Co., of Kansas, are doing all they can to get their patrons to take an enlightened view of dairy farming. No doubt the patrons in Kansas are just about the same as they are in other states, some of them willing to learn the truth and others unwilling. But every patron ought to stop and examine himself in the light of the following questions: "Why is it that the most successful men and the most enlightened farmers and creamery men look at the question one way, and I look at it in another?

Can it be that their intelligence is wrong and my ignorance of the best money making methods is right?

Am I doing what I can to know whether my notions are sound or unsound?

Am I really making any effort to make myself intelligent?

Am I not calling certain ideas impractical, when in reality I have never looked into them to see whether I am right or not?

Have I done anything in particular to make myself intelligent on dairying, in the same way as other men have to do who are intelligent?

Reasoning along these lines, and they are the right lines, the Continental Creamery Co. have issued a booklet for the instruction of the farmers who supply them with milk, and here are some of the things they say:

THE BABCOCK TEST.

The deeper the insight obtained by the patron into the present creamery methods and practices, the better pleased he will be with the results. Likewise the more he knows of the Babcock test and its workings, the less reason or inclination the patron has to complain of the tests of his product when reported from the creamery or skimming stations. If the grocer fails to give the farmer correct weights for his butter, he buys scales and weighs the butter at home. If the creamery patron concludes that the creamery is not giving correct tests why should he not buy a Babcock tester, the use of which will dispel the apparently mysterious things which present themselves?

The Babcock test should be in actual use at every farm in determining for the owner the relative value of his cows. A common notion prevailing among farmers is that profit depends upon the test. If one person has a higher test than his neighbor, it must be that he is getting more profit from his cows. Likewise, if one cow has a test of 3.5 per cent, and another 4.9, then the conclusion is drawn that the 4.9 is by far the better of the two. Prof. D. H. Otis of the Kansas Experiment Station, says: "In regard to the low and high testing for cows, we must bear in mind that the test is only one factor. Frequently more depends upon the pounds of milk than upon the test. Take, for example, two cows at the agricultural college. Cow No. 20, during her first year's record, yielded 9,116 pounds of milk in twelve months, which tested an average of 4.2 per cent. Cow No. 11 yielded 3,475 pounds in the same length of time with a test of 5.1 per cent. A number of farmers, when shown the test of these two cows, have expressed themselves to the effect that cow No. 11 was an excellent cow because she had a test of 5.1 per cent. No. 20, with a 4.2 per cent test, produced for the year 383 pounds of butterfat, and No. 11, with a 5.1 per cent test, produced only 178 pounds of butter fat, a difference of 205 pounds in favor of the low testing cow. No. 20 brought us an income of $40.37 above the cost of feed, while No. 1 brought us only $17.60 over cost of feed."

Are you milking cows which are just paying their board, or are they returning you a profit for labor and feed?

A Babcock tester and a pair of scales will determine for you.

Any bright boy or girl fifteen years of age can easily learn how to run a Babcock test. Give the boys and girls a chance to learn.

THE GERMAN FARMERS IN WISCONSIN.

The party of German Agriculturists who are touring the United States, spent three days of last week in Wisconsin and although the time was brief, they crowded much of sight-seeing and entertainment into the short time they were in the state.

They arrived in Madison from St. Paul on Saturday morning, and spent the day in visiting the Experiment Station and University. Although they had been surfeited with sight seeing in the eleven thousand miles they had travelled, they seemed just as eager to see the things of interest that the Experiment Station had to offer, as if they had just started. Note books and cameras were much in evidence all day.

It was the almost universal comment of the party that agriculture in this country is so different from German conditions. Men, soil, crops and methods vary widely from what they are accustomed to see, and are interesting accordingly. On arriving in Madison they were met at the depot by Dean W. A. Henry of the College of Agriculture, assisted by the faculty, the German members of the State University faculty, and a number of invited guests. The party left the depot in carriages and were driven to Eagle Heights on the University drive. The University horse barn was reached before 10 o'clock, when the tour of inspection began, and the German visitors were treated to one surprise after another at the Wisconsin Station. Dean Henry and the heads of departments were kept exceedingly busy answering questions through interpreters. While a few of the party could read and talk English, a majority could not do so, and the interpreters were called upon continually to explain the meaning of signs and placards hung upon the walls in the various buildings.

From the horse barn the party went to the hog and sheep barns. What attracted their attention there most, was the razor back hogs from Texas, few of the visitors having ever heard of them. Much interest was manifested in the Berkshires, with their sleek and well rounded appearance, and the arrangements for experimental work in feeding hogs and keeping records of individual animals. Many questions were asked and notes jotted down. Dean Henry and Prof. W. L. Carlyle busily explained the methods of feeding and caring for the hogs. Interest was taken in the arrangement of pens and feeding hogs separately, for keeping proper records. After viewing the sheep barns and beef cattle in paddocks, the dairy barn was visited, where great interest was manifested in the manner of keeping cows, arrangement of stalls with the printed record of each cow over the head of the stall. From the cow stables the party went to the live stock judging pavilion, where a light lunch was served.

Leaving the dairy barn on the way to the dairy school building, the experimental plots of farm crops were passed and inspected. The keenest appreciation of the visit, however, was evidenced when the dairy school was reached as the magnitude of the work done there dawned upon them. Exceedingly close inspection was made of the various butter churns, cream separators, pasteurizers, coolers, Babcock testers; in fact, all the utensils used in the manufacturing of butter and cheese were carefully looked over with interest and surprise. When the first members of the party entered the underground tunnel, the passage way leading to the refrigerating rooms in which cheese is being aged by the cold cured process, the greatest surprise of the day was in store for them. This cold curing process of cheese making is a Wisconsin innovation, and a revolution in European methods. Every member of the party took great interest in this experimental work and many questions had to be answered.

The horticultural and physics building was next visited and the visitors were shown through the greenhouses. From here the party moved to the new Agricultural College building, which has just been erected at a cost of $150,000, with its four floors of commodious rooms and auditorium. In passing through the halls and rooms of the large structure, comments of praise were freely heard that the state of Wisconsin should be so liberal in appropriating money for agricultural education. The visitors were given bulletins, pamphlets and pictures of the various departments to forward to friends in Europe.

At 1 o'clock the party took dinner, after which they took a trip on Lake Mendota, back to the University. Here the state Historical Library and the Gymnasium were visited. With the former building the Germans were delighted. A trip was then taken to the farm of S. H. Marshall on Lake Mendota. The visitors then came back to the city, and left on the 6 o'clock train for Milwaukee.

After the Sunday spent in visiting and entertainment in Milwaukee, the party came back to agriculture and spent Monday in a rapid review of dairy conditions in Jefferson county, beginning at Lake Mills where the large Holstein herds of the Fargo Bros. were visited and also the noted Jersey herd of W. P. Phillips. As the Channel Island breeds are almost, if not entirely unknown in Germany, there was much interest shown in Mr. Phillip's herd of butter producers. The Holsteins were of more interest as being closer related to the cattle of Germany and the $1,400 cow, Duchess Ormsby II Hengerveld de Kol, received special attention.

At 2 o'clock the party left the home of the Holsteins for the territory of the Guernseys, reaching Fort Atkinson shortly before three o'clock. On arrival they were driven to the Hoard creamery.

Most had heard of the Hoard creamery before they started on their trip, and they had planned to inspect it critically. Every detail came in for attention, and scores of questions were asked regarding percentages of butter fat and the hygienic methods employed in the plant.

The refrigerator part of the plant was examined after the appliances for making butter had been looked over. From the creamery the party drove to the Cornish, Curtis & Greene factory, where dairy supplies were seen in process of construction, and then the drive led to the dairy farm of the Senior editor of the DAIRYMAN.

Tables had been placed under the trees in the grove surrounding the big farmhouse, and before proceeding to an inspection of the fields and buildings and the herd of Guernseys, the party were invited to seat themselves around the tables and partake of luncheon.

When driving in to the farmyard the visitors had become interested in the fields of alfalfa that met their view, and as soon as luncheon was finished, several of them posted off to inspect them at close range.

After the inspection of the barn and herd the guests returned to the lawn, where there was a season of song and good fellowship, until it was time to catch the train for the south.

A notable feature of the day in the dairy region, and one which was an especial source of pleasure to the visitors, was the participation in the entertainment of sons of the fatherland who had emigrated to this section of Wisconsin and become masters of prosperous estates. Nearly every carriage in which the visitors rode, both at Lake Mills and Fort Atkinson, belonged to a German farmer. The teams were driven by the farmers, who explained everything of interest to the tourists in their native tongue.

The party will sail shortly for home and the first result of the visit will be an official report to the government of what has been noted, with suggestions as to the possibilities of introducing any American methods into German farming. The report will be awaited with much interest as being a comment of intensive farmers on the extensive methods of America.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

Milk and Cheese Yield.

How much full cream cheese can be made from average milk, enough to make 100 lbs. of butter?
New York City. O. G. M.

One hundred pounds of butter contains on an average, 82.5 lbs. of fat. Average milk contains 3.75 per cent of fat; thus the above weight of fat is equal to 2,200 lbs. of 3.75 per cent milk, and this amount of milk will make on an average 222 lbs. of cheese. The above figures are of course average estimates, the actual yield of cheese depends largely on the quality of the milk, and the skill of the cheese maker as well as the richness of the milk, and figures like the above must always be regarded as largely theoretical and subject to revision by practical work.

Registering Jerseys.

F. W. B., Tilden, Wis., writes us as follows:

Can you give me a little information how and where I can have Jersey cattle registered? I bought a cow last fall which is full blood, but not registered, her sire and dam were brought to Chippewa Falls by Ex. Govenor T. C. Pound and were both registered, so I would like to have a number for this one too, as I bought her to raise stock with. She was bred to a full blood sire before I bought her and June 1st she dropped a fine bull calf, which I also would like to have registered. The old cow, his dam, gave 14 lbs. of butter in 7 days, so I think he will make a fine sire to head my herd of high bred Jerseys.

He can obtain the necessary information and blanks by writting to J. J. Hemingway, Secretary of the American Jersey Cattle Club, 8, west 17th street, New York, N. Y.

He may find it a matter of some difficulty to secure the necessary evidence as to the breeding of this cow and her calf, but with patience and perseverance, and possibly some little expense, the chances are that the necessary evidence can be obtained, and it is well worth all it will cost to get such an animal properly recognized and registered.

A Corn Bran Inquiry.

Please balance ration for cows from corn bran, sugar feed, corn and cob meal, and cotton seed meal. Has corn bran more protein than wheat bran, and is it cheaper at the same price?
Daretown, N. J. SUBSCRIBER.

It is not possible to submit a ration formula without information as to the kind and quality of the roughage which may be available. Corn bran and sugar feed are two distinct feeds, although the term "sugar feed" is not recognized as a standard feed, because of its great variability. Corn bran contains 7.4 per cent digestible protein and wheat bran 12.6 per cent, but the former contains enough more carbohydrates and fat to give more than equal feeding value, where one does not especially require protein.

Ventilating a Barn.

C. E. M., Stewartville, Minn., has a barn 24×56 feet containing a silo and hay mow, with lean-tos on one side and one end for cow stalls, and asks how he can ventilate the same in an effective but not expensive way. Feeding alleys run between the lean-tos and the main building.

He should build a ventilating flue or shaft in the main barn, and from the sketch given, we think it might be located adjacent to the silo. This shaft should have a cross section of four square feet for every twenty head of stock, and should rise up through the ridge, if practicable, and at all events, higher than the ridge somewhat. Let there be an opening two feet square or more on a level with the floor, with a door or slide so that it can be opened or closed, in whole, or in part at will. This will draw off the cold and foul air from the floor. Let there be a similar opening on a level with the ceiling of the stable that can be opened and closed at will for drawing off the hot air in the stable in the summer months. This shaft or flue should be practically air tight from top to bottom, just as a chimney in the house should be air tight in order to secure a good draft.

To provide for the entrance of fresh air, let there be at least a half dozen openings a foot square just below the ceiling of the stable connected with flues running down three feet or more and then opening outwards into the outer air. This bend or change of direction in the intake flues will prevent the warm air from escaping and not interfere with the entrance of the pure air from the outside. These openings for the entrance of fresh air should be provided with slides so that they may be closed as occasion may require, letting in more or less fresh air according to circumstances.

Value of Cream of Different Per Cents of Fat.

Will you please give me the proper price per quart for cream testing 30% and 40% butter fat, based on the price of 18 cents per quart for cream testing 22% butter fat? I understand there is a greater loss in quantity, as the per cent of butter fat increases, than the proportion would indicate. Are there any tables published covering the above, also showing the weight per quart of cream of different per cents of butter fat? W.
New York.

A gallon of 30% cream will weigh 8.34 lbs. and will contain 2.50 lbs. of butter fat. A gallon of 22% cream weighs 8.44 lbs. and contains 1.85 lbs. of butter fat. Now, if the 22% cream sells for 72 cents, the 30% cream should sell for 96.2 cents per gallon, or 18 and 24.05 cents per quart. If it is taken proportionally according to the per cent of fat present, the selling price of the quart of 30% cream would be 24.55 cents, a difference of half a cent a quart in excess of the true value. In practical work the weight of a quart of cream varies on account of contained air, and this is sufficient to destroy any practical relations between volume and weight, and probably for this reason no tables covering the above point, have been made.

Handling the Bull.

I have been a reader of HOARD'S DAIRYMAN for several years, studying the weekly issues like an earnest student would his text book.

And to convince you that I have profited by the study, I want to say that I have made my cows pay me a net profit of over $100 per year each.

But unfortunately for me there is one thing I have not yet learned, and that is how to handle a bull. That little bit of ignorance nearly cost me my life last Tuesday, and but for the quick action of my boy, a lad of 17, grasping the bull by the rope fast in his ring, I would now be on cemetery hill. As a result of that escapade, I am pretty badly bunged up.

I regret to be obliged to part with my bull, all on account of not knowing how to handle a creature of that kind. He is a registered Holstein-Friesian; weighs 2,000 lbs., 4 years old. All I can get for him is 2½ cents per pound.

As I am a carpenter by education and not a dairyman, you can judge how it is that I do not know more about handling bulls.

Now, what I would like to see in the DAIRYMAN is an able article by some expert, who can tell how to handle a bull with some fair degree of safety. I want him to tell what kind of a ring he puts in his nose that will not break; what kind of a stick is used to lead him with, and what kind of a fastening at the end of the stick; How to fasten the bull in his stall and give him some chance to move about.

This may provoke a smile in old hands at the business, but with me it is a serious thing and may cost the life of myself or son. T. F. V.
Marshfield, Wis.

It appears from the foregoing letter that the ring in his bull's nose was all sufficient. We have had no difficulty with the common, copper bull rings that are on sale in most hardware stores. We aim to keep pretty close watch of them to see that the rivets do not become too much worn, and after a ring has been in for some considerable time, we either put in a second one, leaving two in the nose, or take out the old one and put in a new one. For a staff, we usually go to the hardware store and select the best fork handle we can find, and put on the end of this, one of the malleable hooks and springs which are also usually on sale in hardware stores. If not obtainable, where this subscriber lives, his hardware merchant will be more than willing to order one or more from the wholesale dealers with whom he trades. Never attempt to take the bull out of his stall without the use of this staff.

As a further precaution, with bulls that are pretty strong willed, we pass a small, strong cord through the ring, across the face of the bull and around the horns. This gives an extra purchase on the nose, lifting it up, and effectually prevents the bull from lowering his head, as bulls are accustomed to do when they charge.

A cross bull is not a very pleasant animal to have on one's premises, but, sometimes, they are much safer animals to handle than a bull that has never exhibited any ugliness or disposition to have his own way, because in the former case, we are continually on our guard, and it is nine points in the battle not to be taken by surprise. We should, therefore, hesitate somewhat to dispose of an animal that suited us in every other respect because he was disposed to be cross. There are none too many first-class bulls in the world, and when one has proven his efficiency, it is worth while to submit to considerable extra trouble and care rather than take the chance of getting a poorer animal. Whenever such a bull is to be handled, there should always be two people present, one with the staff and the other with a rope.

There are various ways for confining a bull. One is to give him the freedom of a strong box stall. This is the plan adopted in the barn of the editors of HOARD'S DAIRYMAN at the present time. The present writer has sometimes tied his bull in a large stall with a strong halter and given him the freedom of a small paddock day times.

The main point, however, in handling a bull, is to be always on one's guard and never give him an opportunity to get any advantage. One should never undertake to drive or corner a bull, for they very soon learn that they can have their own way, and when they have once had it, they are very apt to try it again. We have never had a cross bull on our farms, largely because we train them from calfhood up, never giving them an opportunity to show their strength, but we always proceed on the theory that they may attempt this at any time, and so we are constantly on the lookout to see that they get no advantage.

Poor Churning.

Does abundance of fresh air have any effect on churning? I use a barrel churn and have had considerable trouble since warm weather began. There has been a decrease in both quantity and quality of butter although treated just as it was in cool weather. E. P. S.
Asheville, N. C.

All Babcock testers now on the market are good machines so far as we know, it

"ADVERTISEMENT."

POWERFUL

A Pure Food Drink Has Great Sustaining Power.

The sustaining power of Postum Coffee when properly cooked is greater than most people imagine and it is well illustrated in the story told by a young Texas woman who says: "I almost lived on Postum Cereal Coffee for over a month and there was over a week I did not eat anything at all but just drank the food drink Postum and yet I grew stronger and gained weight.

"Our family physician examined Postum and decided to use it altogether in place of coffee. We all think it has no equal as a nourishment for the sick for beside being pleasant to the taste it is so strengthening. My father and mother have always been coffee drinkers and suffered all kinds of troubles from the coffee until about a year ago a neighbor was prasing Postum and mother decided to try it.

"They improved at once and have drank Postum ever since and mother, who used to be bothered with nervousness and sleeplessness particularly, is in splendid health now. She says the change come entirely from drinking Postum and leaving off coffee." Name given by Postum Co., Battle Creek, Mich.

There are many reasons why the Improved

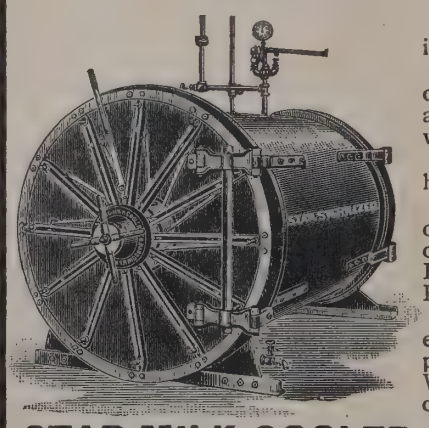
U. S. SEPARATOR IS THE ONE TO BUY

BELOW ARE A FEW OF THEM:

THE U. S.

Costs no more than inferior machines
Gets More Cream out of the Milk
Is less expensive to operate
Increases the quantity
Improves the quality
Will wear longer
Soon pays for itself
Has its gears enclosed
Bowl has few parts to wash
Has simple self-emptying Bowl
Has many other points of superiority
More fully described in our catalogues which are free for the asking, all making

The U. S. Separator the Standard Separator of the World



For Western customers, we transfer our separators from Chicago, LaCrosse, Minneapolis, Sioux City and Omaha. Address all letters to Bellows Falls, Vt.

Vermont Farm Machine Co., Bellows Falls, Vt.

WHEN YOU SEND IN YOUR RENEWAL, SPEAK TO A FEW OF YOUR NEIGHBORS AND HAVE THEM JOIN YOU. CLUB RATES: 2 Subscriptions, $1.50; 3 Subscriptions, $2.00; 4 Subscriptions, $2.50; 5 Subscriptions, $3.00.

COME ALL YE GOOD PEOPLE AND LOOK AT OUR STAR.

Heavy Pressure Sterilizer, which will insure thorough Sterilization. **TRY IT.**

A good thing is not to be lightly passed over. Placing a lot of bottles in a box and giving them a vapor bath is NOT what we call sterilization.

The entire mass of bottles must be heated to 212 deg. Fhr. or over.

Send for our Sterilizer Booklet which contains illustrations and descriptions of our complete Sterilizing Outfit, including Bottle Cars, Bottle Carriers, Reversing Racks, Spacers, Etc.

Sterilizers are becoming a necessity in every Hygienic Dairy, therefore send for prices and information regarding them. We will go into the details with you cheerfully. - - - - - - -

Champion Milk Cooler Co., 67 Main Street, CORTLAND, N. Y.

being entirely a question of material and work. Air has no effect on churning, although many experimenters have spent much time and money to prove that air is advantageous in the gathering of butter. The trouble you have probably comes from changes in the condition of your cream and this may be caused by over ripening or from the presence of bacteria that do not produce the normal lactic acid ripening of the cream. Which of these causes is the active one in your case we cannot say, but a little experimenting on your part would soon show if the cream is ripened properly and has the usual amount of acid present.

Farm Buildings.

We have lately purchased a large farm in this state, 2,500 acres, and intend establishing thereon a model dairy farm to furnish milk to one of our largest national institutions, with whom we have a contract. Could you give us any information regarding building of silos and filling, or refer us to some treatise on this subject, also as to the best kind of corn to be used in planting for silo feed. Also, could you place us in communication with parties who have model barns, that we may get their ideas on this subject. J. V. J.
Newburg, N. Y.

Get King's Physics of Agriculture, $1.75 from this office, for full information on these and thousands of other subjects. There are very few barns that we could recommend as models, and none to our knowledge near Newburg. The best kind of corn for silage is the largest variety that will mature on the farm.

Dairying and Soil Fertility.

The New Jersey Experiment Station has conducted some experiments with the idea of illustrating the extent to which soil fertility is accumulated where dairy animals are kept on the farm. Twenty-three cows in 1896 consumed 9.40 tons of bran, 8.20 tons of dry brewers grains, 6.10 tons of corn meal, and 3.55 tons of linseed meal, these foods containing 1,700 pounds of nitrogen. In 1897 twenty-five cows consumed 12.50 tons of bran, 8.15 tons of dry brewers grains, 3.30 tons of corn meal and 4.45 tons of linseed meal; the total amount of nitrogen in this food being 1,781 lbs. The same number of cows in 1898 consumed 14.50 tons of bran, 10.25 tons of dry brewers grains, 5 tons of corn meal, 3.50 tons of linseed meal, and 1.75 tons of rice meal; this food containing 2,190 pounds of nitrogen. The foods of the three lots mentioned contained, respectively, 958, 1,108 and 1,373 pounds of phosphoric acid; also 462, 562 and 655 pounds of potash, respectively. There was contained in the milk of the twenty-three cows of 1896, 849 pounds of nitrogen, this being 851 pounds less nitrogen than was contained in the food consumed. In 1897 the milk contained 927 pounds of nitrogen, this being 854 pounds less than the amount supplied in the food. The herd in 1898 were supplied in the food, 1,154 pounds more nitrogen than was removed from the farm in the milk. In 1896 there was 640 lbs. more phosphoric acid supplied in the feed than was contained in the milk; in 1897, 761 pounds and in 1898, 984 pounds. of potash the food contained 214 pounds more than the milk in 1896, 291 more in 1897, and 353 more in 1898. To summarize these results, it may be said that during the three years there was a gain of 2,859 pounds of nitrogen, 2,385 pounds of phosphoric acid and 858 pounds of potash; that is, these amounts of the fertilizing elements were left on the farm in the form of barnyard manure after removing the milk. If there is this increase in fertility when the milk is taken from the farm, what must be the result when only the cream is removed? It simply is this, that the amount is practically nil, being less than $1 for every $400 worth of dairy products sold. There is no system of farming that to so great an extent conserves the elements of fertility as dairying, and especially so when only the butter fat is removed and the skim milk left on the farm to be fed to the calves and hogs.

The Art of Testing Cream.

"Testing is a very simple thing." This is an expression used by many who never studied the real nature of testing. The Babcock tester is generally used in this country, while in Europe this tester is looked upon as an inaccurate method. The Europeans employ mostly Soxhlet's tester, the Laktokrit or Wollny's refractometer. Compared with those three named testers, the Babcock is the most simple tester which gives also sufficient accuracy. It is, however, to be regretted that the many manufacturers have made the Babcock tester inaccurate first by putting out inaccurate glassware, and second, their machines are are wrongly constructed.

Now, let us ask what influences the testing mostly, taking for granted that a good sample is taken.

1. Inaccurate pipette in milk testing.
2. Careless weighing in cream testing.
3. Adding water to cream sample.
4. Amount of acid.
5. Strength of acid.
6. Temperature of acid.
7. Temperature of sample.
8. Speed of tester.
9. Length of first running.
10. Quality of water added.
11. Length of second running.
12. Careless reading.
13. Temperature of reading.
14. Inaccurate glassware.

There are fourteen points to be looked after, and if it should happen that one point gets neglected the whole test may be spoiled.

Some states have already passed a law which compels each creamery to have the glassware tested, a law, which every state in the Union ought to have, as inaccurate glassware is causing endless trouble in creamery life.

The color of the fat is a good indication of the proper amount, proper strength, and the right temperature of the acid we use in our testing. The most trouble is caused by weak acid in testing heavy cream, and in winter time by using too cold acid. Another great annoyance in testing, is the amount and the nature of the preservatives used in our samples, as for instance, too much bichromate of potassium causes serious trouble.

One of the main points in testing is reading at the right temperature, which subject was fully discussed by Professor Woll, of Madison, and by the late Mr. Beebe, chemist of the Hazelwood Company. By the way, I think Mr. Beebe has done very much to improve our system of testing. He was an eminent, careful and accurate worker, and he ought to receive due credit for his work. That many of our tests are read too high is simply the fault of the tester, and another great drawback of our testers is the wrong relations between diameter and speed. We know of a tester which, according to the instruction of the manufacturer, should be run not over 750 revolutions per minute, ought to be run at least 800 revolutions to give a fair result, because the tester has a diameter of 18½ inches.

We have conducted a series of experiments in order to find out the relations between test and weight of sample taken, and give the result below:

Weight of cream.	*Weight of sample.*	*Test.*	*Butter fat in lbs.*
	I		
70 lbs. (thin)	1 oz.	33½%.	
70 lbs. (thick)	1 oz.	composite	46.90
	II		
70 lbs. (thin)	1 oz.	34½%.	
70 lbs. (thick)	2 oz.	composite	48.30
	III		
70 lbs. (thin)	2 oz.	32%.	
70 lbs. (thick)	1 oz.	composite	44.80
	IV		
70 lbs. (thin)	2 oz.	29½%	20.65
70 lbs. (thick)	2 oz.	37½%	26.25
			46.90

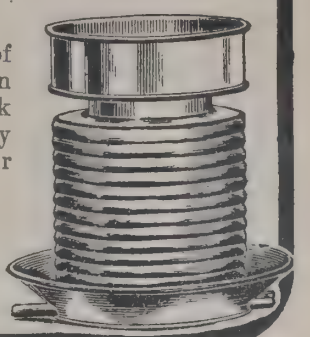
The reader will easily see that the composite test, 33½ per cent, is correct, because it gives us a 46.90 pounds butterfat, the same amount as in No. IV, where each lot was tested by itself.

Taking too much cream out of the can, containing thick cream, with the sample dipper gives us a too high reading, viz, 34½ per cent, and vice versa with the can containing thin cream; the consequence is a like amount must be taken with the sample dipper, provided the weight of each can is alike also.

Weight of cream.	*Weight of sample.*	*Test.*	*Butter fat in lbs.*
	I.		
70 lbs. (thick)	2 oz.		
60 lbs. (medium)	2 oz.	32½%	
40 lbs. (thinner)	2 oz.	Composite	55.25
	II.		
70 lbs. (thick)	2 oz.	35%	24.50
60 lbs. (medium)	1¾ oz.	31%	18.60
40 lbs. (thinner)	1¼ oz.	28%	11.20

Our true average test ought to be: (54.30×100)+ 170(weight of cream)= 31.94per cent. 31.94×170=54.30.

The reader will notice our mistake, viz: taking the same amount out of each can regardless of the amount of cream each can contained.



I do not claim to have made any new discovery. Any up-to-date creameryman knows this all, but I was surprised to find such a big difference, and it simply shows us how careful we must proceed in taking samples.—LUDWIG ENGLEMANN in *The Ranch*.

Did You Ever Keep a Record Of Your Cows?

IF SO, you have felt the need of a convenient, simple and handy Record Sheet. We have had so many requests for these Record Sheets that we concluded to get up one that would "fill the long felt want." We have a very simple and complete Record Sheet for 10 cows, one month, that is printed on heavy Manilla Paper, we can send postpaid at following prices:

Price 5c Each	6 for 20c	12 for 30c	25 for 50c

SIZE 10x16 INCHES

We also have a one cow Record Sheet, heavy Manilla paper (one month) that we will mail postpaid

Single Copy 5c	5 for 15c	10 for 25c	25 for 40c

SIZE 6x15 INCHES

Illinois Herd Reports.

The Report of Herd "C."

ED. HOARD'S DAIRYMAN:—This herd was composed of Natives, Grade Shorthorns, Grade Holsteins, one Red Poll and two Grade Jerseys. The cows weighed on the average, about 1,050 lbs. and were in good health during the whole year. There were no abortions or caked udders during the time the test was made. A number of the cows were sold early in the test because of their rapid falling off in milk flow when about three months along in the period of lactation. This is a very common fault with a great many cows kept in the dairy, and it is not noticed as much as it should be by the owners. They remember the cow when she gave a full pail of milk.

The herd received good care during the year, and was kept in a warm barn during the winter where they received a fairly good ration. The fresh cows in October to November were fed daily about 3 lbs. of bran, shock corn and pasture. From Nov. 15th to Jan. 1st., the ration consisted of the following food: bran, 5 lbs.; corn meal, 3 lbs.;corn stover *ad libitum*. If the farmer could have given his cows 10 lbs. of alfalfa or clover hay and less corn stover, it would have been a considerably better ration for his cows. In Jan. and Feb., a little better ration was fed. It was about as follows:

FOOD STUFFS.	Lbs.	Dry Matter.	Protein.	Carbo-hydrates.	Fat.	Cost.
						Cents.
Bran	5	4.42	.645	2.005	.170	4.5
Corn meal	5	4.45	.395	3.335	.215	5.0
Gluten feed	1	.90	.233	.507	.027	1.1
Timothy hay	5	4.34	.140	2.170	.070	2.5
Corn stover	12	7.14	.204	3.888	.084	2.4
Total nutrients		21.25	1.617	11.905	.566	15.5

This ration would have been still better if the corn meal had been reduced 2 lbs. and gluten feed increased to 4 lbs. During the months of March, April and May, to the cows giving the largest flows of milk were given the following ration:

FOOD STUFFS.	Lbs.	Dry Matter.	Protein.	Carbo-hydrates.	Fat.	Cost.
						Cents
Bran	5	4.42	.645	2.005	.170	4.5
Gluten feed	2	1.80	.466	1.014	.054	2.2
Oil meal	1	.91	.293	.327	.078	1.4
Timothy hay	15	13.02	.420	6.510	.210	7.5
Total nutrients		20.15	1.824	9.856	.512	15.6

The cows were turned out to pasture about the 20th of May, and as soon as the grass was plentiful they received no grain during the rest of the test. They, however, received some forage in connection with the pasture. Green peas and oats were fed in July, and in August green sorghum. It can be said that the herd was well cared for the whole year, and moreover, every cow was fed as near as possible according to the amount of milk and butter fat that she was yielding. It must be borne in mind that the rations given above were fed to cows that were producing the most milk and butter fat, and not to the strippers.

"Crazy" produced the most butter fat in this herd. She gave 6,945 lbs. of milk, 4.23 per cent fat, 294 lbs. of butter fat or 343 lbs. of butter.

"Harrison" produced the least butter fat. She gave 2,722 lbs. of milk, 3 96 per cent fat, 108 lbs. of butter fat or 126 lbs. of butter.

The average production of each cow in the herd was 4,942 lbs. of milk, 3.90 per cent fat, 193 lbs. of butter fat or 225 lbs. of butter.

"Jersey" produced butter fat the cheapest. She charged 29.7c to produce 100 lbs. of milk and 6.6c to make one pound of butter fat.

"Harrison" charged 97.7c to make 100 lbs. of milk and 24.6c to make one pound of butter fat.

The average cost of this herd to produce 100 lbs. of milk was 55.5c, and 14.2c to produce one pound of butter fat.

"Jersey" gave a profit of $34.77, and Harrison charged $1.27 for her keeping.

The average profit for each cow in the herd was $16.22.

Elgin, Ill. A. J. GLOVER.

Meeting of Eastern Guernsey Breeders' Association.

You are requested to attend a meeting of Guernsey breeders at the home of M. M. & E. J. Hollingsworth, Landenberg, Pa., on Friday, June 12th, at 10 o'clock a. m., at which time it is proposed to form an association, the object of which shall be the promotion and encouragement of breeding Guernsey cattle: Hon. E. T. Gill, Hon. Anthony Higgins, Edward Trotter Price, E. J. Hollingsworth, S. I. Murphy, Dr. E. B. Voorhees, M. M. Hollingsworth.

In response to the foregoing call a number of breeders assembled and on motion of the hosts, Hon. E. T. Gill was elected temporary chairman and S. I. Murphy temporary secretary.

Mr. Gill, on taking the chair, stated that the object of the meeting was to form an association composed exclusively of persons who were directly interested in the breeding of registered Guernsey cattle.

The subject was then thoroughly discussed by the breeders present, and it having been decided upon to form such an association, the chairman appointed Messrs. M. M. Hollingsworth, J. L. McCormick and Edward Twaddell a committee to draft a constitution and by-laws.

After the committee had made their report the secretary read the constitution and by-laws as drafted by the committee, and they were then adopted by the breeders present.

The organization, which is to be known as the "Eastern Guernsey Breeders' Association," then elected officers as follows:

President, Hon. Anthony Higgins, Wilmington, Del.; 1st vice-pres., Hon. E. T. Gill, Haddonfield, N. J.; 2nd. vice-pres., George Wood, Philadelphia, Pa.; sec'y. and treas., M. M. Hollingsworth, Landenburg, Pa.; members of executive committee, Edward Twaddell, Devon, Pa.; J. L. McCormick, Bell Air, Md.; S. I. Murphy, Woodbine, Pa.

This concluding the business for the day, the meeting adjourned.

After partaking of the excellent lunch, which had been prepared, the party carefully inspected the Guernsey herd which now contains about sixty registered animals. The older members of the herd are largely the get of Landenberger 2981, and Count Rosendale 3957, the latter a full brother to Prince Rosendale, who was first prize and sweepstakes Guernsey bull at the Pan American Exposition.

The sires now in service are Sir Coral 5239 and Glenwood's Sheet Anchor of Haddon 6372. Sir Coral is by Sir Fantine, who was a son of Mr. Solverson's famous Fantine 2nd, record 23.5 pounds butter in 7 days, 607.7 pounds in 1 year. His dam was Coralette 5722, record 17 pounds, 2 oz. butter in 7 days, 560 pounds in one year and who was 1st prize cow at Wisconsin State Fair, and dam of Coralette's son, who heads the herd of Messrs. Geo. C. Hill & Son, Rosendale, Wis. His oldest daughters are just beginning to freshen and two of them are now being tested for the advanced register. Glenwood's Sheet Anchor of Haddon was bred by Mr. E. T. Gill, of Haddonfield, N. J. His sire, Mainstay has one daughter in the Advanced Register, and is a son of the famous prize winner, Sheet Anchor and Rutila's Daughter, the latter has a record of 21 pounds, 9 oz. in 7 days and 571 pounds in 1 year and has one Advanced Register daughter.

His dam, Glenwood Girl 7th 9114, record 506.5 lbs. butter in one year, 14 lbs., 5¾ oz. in 7 days, was sired by Pat of Haddon who has four daughters in Advanced Register and has for dam Imp. Glenwood Girl, who was the dam of six daughters with records from 504 to 667 lbs. butter in one year.

None of his daughters are yet in milk, but he is being largely used on the get of Sir Coral and his offspring will combine the blood of many of the most famous animals of the breed.

The next meeting (the date of which will be fixed later) is to be held at the home of Mr. E. T. Gill, Haddonfield, N. J.

Woodbine, Pa. S. I. MURPHY.

Are Concentrated Feeds Necessary?

Mr. Grote Continues the Discussion.

"The teacher easily becomes imprisoned in yesterday's knowledge, in yesterday's methods. He is too prone to look back for details, instead of looking about him for present inspiration."—Page 390.

ED. HOARD'S DAIRYMAN:—When I sent in my questions, I did not intend to have a controversy with the Editor. My aim was to get the established facts; the "proof" which sustained the Editor's position that "a cow of pronounced dairy temperament cannot eat and digest enough roughage to furnish sufficient raw material from which to elaborate milk up to her capacity," and, "we think that cows will do fairly well on clover silage and clover hay alone, but better and with more profit if they have some grain in connection."—Page 258.

The right decision on these points is of great importance to the dairyman, and an intelligent dairyman is not satisfied with the conclusions of others. He claims the right to examine into the facts himself, and from them form his own conclusions. A teacher offering a theory should always be prepared to defend that theory by producing the established facts which sustain his theory. The feeding problem of cows is not yet fully solved. It is a great question yet unsolved, if the feeding of concentrated feed is a benefit to the cow, and at the same time increases the net profits of the dairymen. Any facts and figures which give light on these points should be welcome to every reader of the DAIRYMAN, but the evidence should be furnished as much as possible in detail.

It is immaterial in this inquiry whether a woman prejudges the damages which a mouse, a little harmless snake, lizzard, toad or bug can do on account of the peculiar cut of her clothes, or for other reasons, so as to induce her to climb on a chair or table, or whether she prejudges those animals on account of her ignorance in regard to them or their habits. It is my opinion that the latter is the cause. Ignorance, or only part information, or misunderstanding is the cause of all prejudice or prejudgment.

It is also immaterial whether a farmer, living 10 to 30 miles from railroad where he could sell or exchange produce, hauled over poor roads, where 2,000 lbs. is a good load, can lose 2 or 3 days for a man and team to exchange one ton of feed and make the transaction practical and profitable.

It is also immaterial for this inquiry that thousands upon thousands of successful dairymen do purchase feed and do exchange feed raised on the farm for by-products. A large number of good farmers do not.

The question is? Is it profitable for the farmer and necessary for the cow to purchase this expensive feed, or can a more profitable system suitable to all farmers be substituted?

If experience has demonstrated that an average good cow cannot dispose of more than 25 lbs. of dry matter during 24 hours, it has also demonstrated that a cow will starve if the 25 lbs. dry matter does not contain the proper digestible nutrients, and it has also demonstrated that 25 lbs. proper dry matter, is about all the dry matter that 99 per cent of the existing cows are able to digest properly.

An experiment in Madison, Wis., did show that an increase of the concentrated food of the ration from 8 to 12 lbs. did not give sufficient increase in milk to pay the additional cost. It is necessary that the feeder must have common sense. There are a number of rations that can be raised on the farm and at a considerably less cost than buying by-products, which have no more than 25 lbs. dry matter, containtng sufficient digestible nutrients to furnish 90 per cent of the existing milk cows with proper digestible nutriments, to sustain their milk flow up to their full capacity. (See the clover ration.)

If the DAIRYMAN can prove that the more expensive ration gives so much more income that the additional income will cover the extra expense and labor and leave in addition a surplus, the DAIRYMAN has done a service to the whole dairy business, and we will all acknowledge its superior sagacity. This requires facts and figures. Let us have them. It is a business proposition and has to be decided on its merits alone.

The fact that juries so often fail to agree and that people disagree on the tariff proves only that different people draw different conclusions from the same facts, or that the comprehension of the different people is not equally advanced, or is misled by pre-formed opinions. The facts must, therefore, be so plainly proven that all persons must come to the same conclusions and acknowledge that the facts have been established for all minds.

There are a number of questions which require settlement besides the one of most profiatble feeding, such as the question of raising fodder corn (which I think is very important) but the feeding question, the prejudice that concentrated food is a necessity under any circumstances to successful and profitable feeding, has either to be proven or disproven.

Mauston, Wis. CHAS. N. GROTE.

Butter-Tests Accepted for Publication by the American Jersey Cattle Club, June 18, 1903.

Chocolate Maid 131035: Sire, Brown Bessie's Son 11th 50830: dam, Miss Newhouse 92487. Butter, 14 lbs., 8 oz.; milk, 204 lbs., 13 oz. Test made from Jan. 30, to Feb. 6, 1903; age, 3 years, 6 months; estimated weight, 800 lbs.; fed 9 lbs. oats, 9 lbs. bran and shorts, 1½ lb. oil meal and 15 lbs. sliced potatoes, daily. hay *ad. lib.* Property of Estate of W. S. Ladd, Portland, Oregon.

Cretesia's Ramona 148867: Sire, Cretesia's Albert Pogis 21730; dam, Ramona B. 52135; butter, 15

lbs. 4 oz., milk, 1236 lbs., 8 oz. Butter, 15 lbs., 4 oz.; milk, 236 lbs., 8 oz. Test made from Nov. 16 to 22, 1902; age, 9 years, 4 months; estimated weight, 950 lbs.; fed 6 quarts middlings, 6 quarts bran, 1 quart corn meal, 1⅓ quarts of a mixture consisting of one part gluten to two parts cotton seed meal, 1⅓ quarts oil meal and 1¼ quarts gluten, daily.

Imported Grace Darling, 145737: Sire, Beauty's Grevcoat P. S. 2248 C.; dam, Alouette P. S. 6958. H. C. Butter, 15 lbs., 3 oz.; milk, 201 lbs., 4 oz. Test made from April 12 to 18, 1903; age, 5 yeare, 2 months; estimated weight, 850 lbs.; fed 9 quarts bran, 30 lbs. ensilage, 1⅓ quarts oil meal, 1⅓ qts. gluten and 1⅓ quarts of a mixture consisting of one part oil meal to two parts of cotton seed meal, daily.

King of St. L.'s Jewel of C. H. 130559: Sire, Coal Hill King of St. L. 32996; dam, Charity of Pittsford 2d 88849. Butter, 15 lbs., 8 oz.; estimated fat, 13.266 lbs. milk, 303.8 lbs. Test made from May 11 to 17, 1903; age, 7 years, 2 months; actual weight, 880 lbs.; fed 18¼ lbs. bran, 18¼ lbs. linseed meal, 18¼ lbs. corn and cob meal and 105 lbs. ensilage; blue grass pasture. Property of Ohio State University, Columbus, Ohio.

King of St. L's Jewel of C. H. 130550, 14 days; Butter, 29.6 lbs., estimated fat, 25.723 lbs.: milk, 601.6 lbs. Test made from May 11 to 24, 1003; age, 7 years, 2 months; actual weight, 880 lbs; fed 39¼ lbs. linseed meal, 39¼ lbs. bran, 39¼ lbs. corn and cob meal and 210 lbs. ensilage; blue grass pasture. Property of Ohio State University, Columbus, Ohio.

Lemorna 02879; Sire, Signia 29385: dam, Avonola Waif 66778; butter, 17 lbs.; milk, 302 lbs. Test made from May 21 to 27, 1903; age, 9 years, 8 months; estimated weight, 800 lbs.; fed gluten feed and bran; pasture.

The Relation of Cream to Butter.

Will you please let us know through your paper the difference in the test of a given amount of cream and the amount of butter it will make? I am shipping cream, and while we made 38 lbs. of butter from 100 lbs. cream we only got 28% test. It may be right, but it does not look so to me.

Chandler, Okla. K. F. duM.

It is entirely practicable to obtain an overrun of 18 to 20% of standard commercial butter from cream testing 30% or more fat. It follows, therefore, that cream yielding 38 lbs. of butter from 100 lbs. cream would test about 32% fat. Cream testing 28% fat would make approximately 33 lbs. butter per 100 lbs.

DAIRY MARKETS.

ELGIN, Ill., June 22.—Butter—Ruled firm on board of trade today at 21c. The sales of the week were 830,000 pounds.

CHICAGO, Ill., June 22—Butter—Easy; creameries, 16@20¾c; dairies, 15½@18c.

Eggs—Easy; at mark, cases included, 12½@13¾c.

Cheese—New steady; Twins, 10½c; Daisies, 10¾@11c; Young Americas, 11@11½c.

Cattle—Plain beeves, 1,200 to 1,500 pounds, 5.50@5.70; choice to extra steers, 5.10@5.45; fair to good export and shipping steers, 4.85@5.05; medium beef steers, 4.50@4.75; plain beef steers 4.20@4.35; common to rough, 1,000 to 1,200 lbs. 3.75@4.10; good to choice feeders, 3.85@4.75; good to choice fat heifers, 4.10@5.00; poor to plain stockers and feeders, 3.80@4.00; fair to good cows and heifers, 3.30@4.00; good cutting to fair beef cows, 2.45@3.20; common to good canning cows 1.50@2.40; bulls, poor to choice, 3.20@4.30; veal calves, good to fancy, 5.50@6.75; calves, common to fair, 3.25@5.75: corn-fed western steers, 3.85@5.25; Texas bulls and grass steers, 2.75@3.50; Texas steers, fair to common, 3.85@4.60.

Hogs-Good to prime heavy shipping 6.05@6.15; good to choice heavy packing 5.95@6.10; plain to choice heavy mixed 5.95@6.10; selected butcher weights 6.05@6.12½; assorted light, 150 to 195 lbs. 6.05@6.12½; common to good light mixed. 5.95@6.05; thin to choice, 50 to 130 lbs. pigs 5.70@6.05; stags and rough lots, 5.70@6.05.

MILWAUKEE, Wis., June 22.—Butter—Creamery—extras, 21c; firsts, 18@19c; seconds, 16c; process (renovated) 18@19c: Dairy, fancy, 17c; lines, fresh, 14@15c; packing, 13c; whey, 10c; grease, 5@6c.

Cheese—American, new, full cream—Twins, 10½@11c; Young Americas, 11@11¼c: Daisies, 11@11¼c; Longhorns, 11¼@12c; low grades, 9@10c. Brick, fancy, new, 10@10½c: low grades, 9@10c. Limburger—Fancy, old, 10½@11c; low grades, 8@9c; new, fancy, 9@10c; off grades, 7@8c; Swiss, drum, old, choice, 15¼@16c: drum, No. 2, 13@14c; Block, choice, 14@14½c; block, No. 2, 12@13c.

Eggs—Strictly fresh laid, cases returned, 14c; dirties and seconds, 12c., checks, 10c.

FOND DU LAC, Wis., June 22.—Cheese—Sales of cheese today on the dairy board were 128 Twins at 10¼c, 21 at 10⅜c, and 340 Daisies at 10⅞c. Market active.

SHEBOYGAN, Wis., June 17—Cheese—On the Call Board today 2,557 boxes of cheese were offered and sold as follows: 36 boxes Twins at 10¼c; 22 at 10⅜c: 321 Daisies at 10⅞c; 902 at 10¾c: 65 cases Young Americas at 11c; 538 at 10⅞c; 95 cases Longhorns at 11¼c; 566 at 11⅛c, Demand strong and ultimate brisk bidding.

Eggs—Higher, 13c loss off.

KANSAS CITY, June 22.—Eggs—firm; Missouri and Kansas, cases returned, 11½c doz.; new No. 2. white wood cases included, 12c.

NEWARK, N. J., June 22—Butter-Market steady at 21¼c.

Eggs—Firm at 18@18½c.

NEW ORLFANS, La., June 22—Butter—Extras, 22@22½c; firsts, 21c; ladles, 16½c.

CANTON, N. Y., June 20—Cheese — Offered 55 large, 2,803 Twin cheese and 1,300 tubs of butter. Large and Twin cheese sold at 10¼c; butter sold at 21¼c.

NEW YORK, June 22—Butter—Receipts, 9,200 pkgs.; market steady; state dairy, 17@21c; extra creamery, 21½c; creamery, common to choice, 18@21c.

Eggs—Recipts, 12,656 pkgs.; market steady; state and Pa. extra, 18½c; firsts, 16@17c; western extra, 18½c; western, seconds to firsts, 15@17c.

Cheese—Receipts, 1,901 pkgs; market steady; state full cream, fancy, small white and colored, 10¾c; large, white and colored, 10¾c.

UTICA. N. Y., June 22.—Cheese—Market about the same as last week; 1,200 large white cheese and 2,000 colored at 10½c; 3,500 small colored and 1,500 white also at 10½c.

NEW YORK MARKET.

NEW YORK, June 20—Butter—Receipts for the week, 64,414 packages. Exports for the week, none.

Notwithstanding the large receipts, our market has been steady and at the close reecivers are asking a fraction more than quotations for extra butter, and many lines were put in freezers on speculation.

Trade has taken freely of finest creamery butter, and 21½@21¾c was freely paid by local dealers, and we note sales to southern and eastern trade of firsts and seconds 19@21c. New York dairy of finest quality is wanted at 20½@21c; most of the arrivals, however, were of poor to good grades and sold at 16@20c.

Ladle goods are accumulating and with exporters entirely out of the market, prices were weak and in buyers' favor. We quote:

Creamery, extra, 21½c: medium, 20@21c; poor, 16@19c; Dairy, extra, 20½@21c; medium, 18@20c; poor, 15@17c. Ladle, extra, 17@18c; medium, 16@16½c; poor, 14@15c.

Cheese—Receipts for the week, 42,658 boxes. Exports for the week, 11,719 boxes.

Most of the fine cheese here this week were sold on the docks to speculators who paid 10¾@11c for Cheddars and 10¾c for small sizes, and all went into cold storage for later market.

Exporters took fancy large cheese at 11c, and bought freely of middling grades skimmed cheese at 5@7c. Market closes firm. We quote:

Full Cream, extra, 10¾@11c; medium, 10@10½c; poor, 8@9c.

Eggs—Receipts for the week, 71,411 cases.

The market is filled with poor lots of eggs from all quarters. These goods are freely offered at lower and irregular prices. Strictly fancy fresh stock, however, is not plentiful and is in demand as it always is at full prices. We quote:

N. Y. & Penn., fancy stock per doz., 19@20c: Northern & Western fancy stock, 18@18½c: All sections, poor to good, 13@17c.

177 Chambers St DAVID W. LEWIS & Co.

LIVERPOOL, June 22—Butter—Good United Sates steady, 75s.

Cheese—American finest, white quiet, 53s; colored, quiet, 55s.

Very Low Rates to Denver, Colorado Springs, Pueblo and Return—Via the North-Western Line, July 1 to 10, inclusive, with final return limit until and including August 31, 1903, account of C. E. Convention, Stop over privileges and choice of routes. Side trips can be made at reduced excursion rates to various Colorado points, to the summit of Pike's Peak, to Ogden and Salt Lake City, (to Yellowstone National Park, from Denver, only) and to San Francisco, Los Angeles, etc. Low rate excursion tickets to Colorado also on sale daily, limited for return until Oct. 31. For particulars apply to ticket agents Chicago & North-Western R'y. 20-3

Alfalfa East of the Mississippi.

The *Practical Farmer* correspondents give their experience with alfalafa as follows:

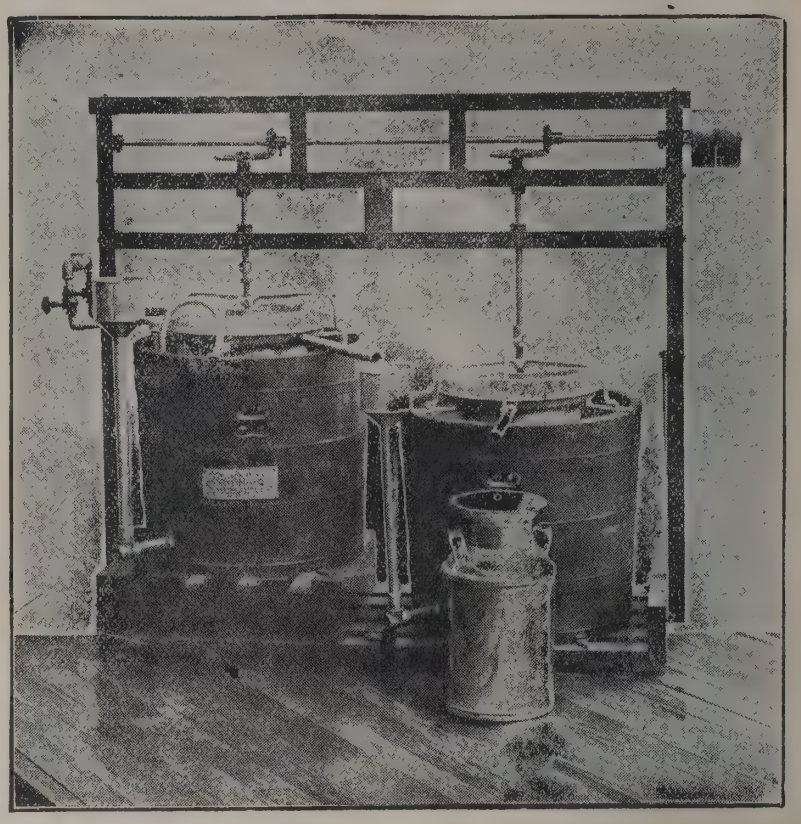
For the past five years I have been experimenting with alfalfa in a small way here. During this time I have tried sowing it with wheat after the manner of sowing red clover, but got no alfalfa. Have sown it in the fall, and it came up well, but not much of it was left in spring. Have sown it with the oat crop with partial success. Have tried light seeding of oats with it as a nurse crop with still better success, but had the best results from sowing alfalfa alone—sown about the first of May, on land that had been plowed early in April and kept well worked for three or four weeks before sowing. The piece was clipped over twice the first season to cut back the alfalfa and the weeds. My soil is high, gravelly clay loam inclined to be dry. Last season I had two acres for cutting. It was three years sown and I got four cuttings. The first crop was the heaviest and yielded about with red clover. The later cuttings were not so heavy, but made finer hay. I have learned to cut just as the first blooms begin to show. If let stand a few days longer the leaves will drop and the stems become woody, and the growth of the next crop will not start up so readily. I am feeding alfalfa hay now, both to work horses and milch cows. It is all right. Have cut much of it and fed it to hogs without curing, but lost a good calf by feeding it alfalfa in this way. I do not care to take the chances of pasturing cattle on it. In parts of the field where the growth was light I treated it to a good dressing of barnyard manure, but could see no improvement. Then tried wood ashes, and was so well pleased with the results that I have used eight tons on two acres. I think the benefit was due mainly to the lime in the ashes. Part of the field is now starting on its fourth year and seems to be better than ever. On account of its permanent nature alfalfa is not so well suited as red clover to a place in the crop rotation, but I believe that a few acres of alfalfa meadow on each farm, to be fed in the winter along with the corn and fodder, will about settle the question of a balanced ration for winter feeding.

I have an acre of alfalfa, seeded in the spring of 1900. It yielded nothing until last year, when I cut it four times, making one and a quarter tons per cutting. Having seen it growing in the west, I was much impressed with its value, and made four attempts to grow it before succeeding, and this is in the face of Prof. Massey's warning not to try it east of the Mississippi river, as it would only make a feeble, sickly growth and soon give up the struggle. I tried it first by sowing with oats. Being dry, so few seeds grew that the ground was plowed and sown to grass. Two years later, in mowing over the ground, I discovered a very thrifty alfalfa plant in full bloom. I reasoned that if one plant would grow successfully, more would. I sowed another small patch that made a good growth the following fall, but cattle ran on it and tramped it out during the winter. The next trial was on ground too flat and wet, and it froze out. The last, sown three years ago on a dry hillside, with oats, nearly perished in the memorable drought of that year, when all clover and much grass died. Up to this time it looked as though I had better have taken Prof. Massey's advice, and let alfalfa alone, but persistence sometimes brings its reward, and on the 8th of May, 1902, there was a uniform growth 20 inches high before the pastures would afford a bite of grass. At present it is more promising than ever, and I am sowing ten acres this spring. The final success is doubtless due to the bacteria and root tubercles, which did not appear till last year. My soil is white oak loam, that shades off into tough, heavy clay in places, the alfalfa doing about as well there as elsewhere. I confess to a little pride over my success now in spite of the past, not present, teachings of Prof. Massey, and the adverse criticism and opinion of all my friends and neighbors.

[This only shows that none of us are too old to learn. For over thirty years we had seen only failure, as a rule, with alfalfa in the east and had concluded that the trouble was climatic. But we have learned that the fault was with ourselves and not with the climate, and that when properly managed the alfalfa crop is as certain and valuable in the east as elsewhere, and is certain to become a standard meadow crop all over the land, north and south.—ED.]

I believe there is no crop that pays better for the amount of work than alfalfa. After the severe winter of '97, which killed off our clover, I decided to try alfalfa. With no experience to back me I bought 100 pounds of seed, and sowed it with the oats in the spring as we do clover. By the time the oats were cut, it stood a foot high all over the land. The next year we harvested three crops, and in 1901 three crops, which made 13 large loads of hay from the five acres, on an 8×16-foot rack, and the season was dry. Last year we made three cuttings and got 15 loads of hay from the same field. For the benefit of those who would try it, I would state that after the first year it is best to disk it in the spring, and then smooth with a harrow. You may think that this treatment would kill it, but it will not. It will kill the weeds that have started, and send the alfalfa along at a double quick. The land on which we raised this, is near the timber, clay soil on part, and on one end a sandy loam with a sandy subsoil. There is no better paying crop, for everything from a hen to a horse will eat and thrive on it.

We know from experience that there is much land in New York that, properly fitted for the crop, would make four to five tons per acre of alfalfa hay, where farmers are now getting two tons per acre of cured hay. It should not be sown on land in regular rotation with other crops, for it will hold the land for many years if cared for. It has done finely for me on our creek bottom with black muck soil and no hard-pan below, similar to much prairie soil. It will do especially well on limestone soil and on some gravelly lands. A farmer should try some of his best land near the house to save travel. Alfalfa will not thrive among weeds or with grasses like orchard grass. The soil should be tilled and cultivated thoroughly in hoed crops for two years, such as cabbages, corn, potatoes and beans, to clean out the weeds and weed seed. Then plow and fit the land as for a garden. This labor will pay well once in 12 years. Sow 25 to 30 pounds of seed per acre to get a thick stand over the land. Sow last of April or first of May in this climate. Go over with a light harrow and then roll. Some say use no nurse crop, but I would sow not over one bushel of oats per acre with the alfalfa. These shade it just right in dry weather. It should be cut as soon as the first blossoms start and it will branch and thicken up better. It needs more curing than other clover, and mainly in the cock.



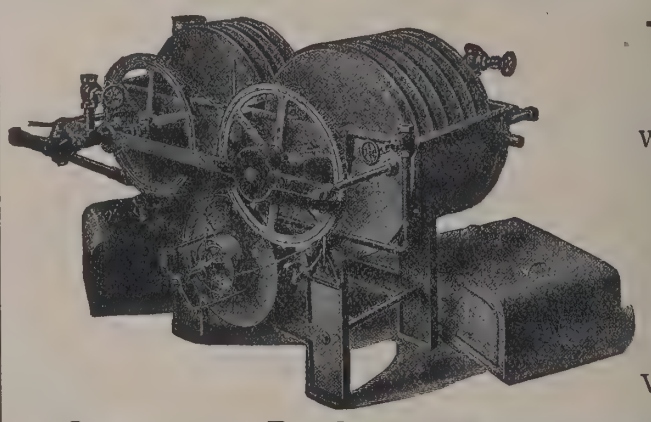
I have sown a small piece of alfalfa as an experiment on a pea stubble in drills 18 inches apart and quite thickly in the drill. I had a good stand and it was three inches high in late November, when I scattered fresh manure over part of it. The rest I let go bare. Cold did not seem to affect it much, but a few warm, balmy days this spring, and then a sharp cold night bit the tops some, but did not kill it. Where the manure was put in November one-half the plants are killed, and there is a bad stand, but where no manure was put there is a good stand and is doing well. I sowed the seed the 23rd of September, 1902, on well drained upland soil somewhat sandy, with a porous subsoil. The alfalfa cannot contend with weeds, and I have cultivated and cleaned mine. I think as a rule, that cow peas are the best crop here as clovers do not do well, and peas do well with little care.

[You should clip the crop over as soon as it shows signs of blooming, whether large enough for hay or not. This season will be the critical time with it, and it should be mown several times to strengthen the roots. A moderate application of lime will help it wonderfully.—Ed.]

I have found alfalfa one of the most profitable crops that can be grown, and to a dairyman almost indispensable, being so near a perfect ration. Some people here claim that they cannot grow it, as it will winter-kill. But this has not been my experience. It is sure death to alfalfa to try to grow it on wet land. It must be sown on land that is dry and the richer you make it the better, for heavy manuring will give you heavier crops. I sow 16 quarts to the acre, and usually cut three times during the season.

Little alfalfa is grown here. Twelve years or more ago a neighbor who had a brother in California who was always ad-

A GREAT SUCCESS.



The Miller Cream Pasteurizer has a capacity of from 450 to 600 lbs. per hour.

vocating the use of alfalfa in the east, sent his brother some seed, which he sowed on new land. It made as fine a stand as anyone could wish, and staid there for years unaffected by cold or dry weather. This caused others to try it, but in every case it was a complete failure. Part of the seed did not seem to grow, and that which did made a very poor showing. It was short lived, and both cold and heat seemed to affect it, while medium red clover made two or three tons per acre right alongside of it. So the farmers here are of the opinion that it is not suited to this climate, as clover has proved superior to it every time.

[The fact that it did well in one instance shows that the climate is not at fault. The failures are just what have occurred all over the east in times past. But now that we are learning the needs of the plant there is no doubt that on proper soil it will succeed with you. Not that it should or is ever intended to supersede red clover, but as a standby and a permanent meadow that can be relied upon in seasons when too dry for the clover.—ED.]

Alfalfa has been successfully grown by three generations of my family in Georgia, since 1838—on the sea coast, in Middle Georgia, in Baldwin Co., in Bartow Co., and in Dade Co., Georgia. Alfalfa does not mind the texture of the soil, if it is rich enough. It is useless to sow alfalfa on poor soil. Our plan has been to prepare the land most thoroughly, plow deeply and cross plow, and harrow till all lumps are fined. Twelve pounds of seed per acre, sown in drills 18 inches apart and covered lightly. Sow in April. Keep clean the first year by plowing with a narrow plow and smooth with the smoothing harrow. Cut twice the first year. It will be at its full growth the third year, but will give three good cuttings the second. Top dress heavily with well rotted manure every third year. Five tons per acre of the best of hay is not an uncommon yield. Here our first cutting comes early in April, a month before red clover can be cut. For soiling, an acre near the stock lot is invaluable. As horses on light work need but one feed of grain daily if they have alfalfa freshly cut twice a day, it comes in well. Four or five cuttings a season are needed. Mow as soon as the alfalfa begins to show bloom. One acre well planted will furnish green and dry fodder for five horses for a year. For milch cows it is the finest of food. The root strikes very deeply, and if well cared for the alfalfa will last twenty years or more. Every farmer in the south should have at least five acres in this valuable forage plant.

SUMMARY.

We have never before had so complete a discussion of the alfalfa question in the East. We have had the topic up before in past years, but the experience in the eastern part of the country has seemed to be against its success. For one, the editor, as is well known, had come to the conclusion that the alfalfa crop was not for us, as a rule, east of the Mississippi River. Mr. Bryan's practice is not a bad one at all, but it has been found that broadcast sowing and clipping will take the place of cultivation in rows and keep the weeds down. The great fields we saw a few days ago on the Occoneechee farm of Col. J. S. Carr, near Hillsboro, N. C., now a number of years old, were broadcasted and clipped and limed. Next spring it is the intention, we believe, to disk these fields over thoroughly and fertilize to renew the growth. It has been found that when the crop is a number of years old this disking and thorough chopping of the whole surface is of great advantage to the crop. Col. Carr has now about 25 acres in alfalfa, having broken up one field this season, and has also sown another large field to take its place. He is growing alfalfa as a money crop for the hay, which he sells in various parts of the country at a remunerative price. We are firmly of the opinion that south of the Potomac at least, if not somewhat north of that line, the sowing should always be done in the fall. Weeds trouble the young plants much less at that season, and a fairly good crop can be had the following season, after liming the young growth in the spring. The essentials in the production of alfalfa seem to be a strong soil well drained, clipping two or three times the first season, and an occasional dressing of lime. A plant of good size pulled from the soil will show few, if any, root tubercles, for they seem to be mainly on the smaller roots and further down than in most legumes. Dig a plant carefully and the tubercles will usually be found. Of course a plant that produces such a heavy growth draws heavily on the mineral content of the soil, and the fertility of the land must be kept up. Stable manure is good, but it is lacking too much in phosphoric acid and potash and tends to weeds. An annual dressing of acid phosphate and muriate of potash will be found better on most soils, and lime must be supplied once in four or five years. The time is close at hand when every farm North and South will have its permanent meadow of alfalfa, just as they now have a permanent pasture. Alfalfa is not intended to supersede red clover in the North or cow peas in the South, for it is not a plant to take into the regular farm rotation. But as a standby it will be found invaluable, and as in Col. Carr's case, it can be made a very profitable money crop.

A Kansas Man's Analysis of the Dairy Business.

(By W. F. JENSEN, Secretary and Treasurer of The Continental Creamery Co.)

Has it ever occurred to you that the most prosperous countries make a leading issue of the dairy business? The richest and most contented states in the Union are those wherein the farmers depend on dairying to a large extent. In making a trip through Northern Illinois, Southern Wisconsin, the New England states and New York state, the traveler is impressed with an apparent barrenness of the soil, and yet he sees on all hands fine dwellings and barns. The many millions of dollars that were loaned to farmers in the west, by eastern loaners, were largely the savings of those people of the rocky hills and fields in the east, who seem to get from their herds of dairy cows, a nice, comfortable living, and in addition a nice, comfortable bank account. The longer I live here in Kansas, the more I am impressed with the fact that a great many of the Kansas people are neglecting their opportunities and neglecting their possibilities to extract from their farms their greatest values in return for their labor and possessions. There is no question but that butter and cheese at the present value, which is 3 or 4 cents higher than it has been for a number of years, is better than any other line of farming; besides it lends to farming a certain stability and assured income. And we all know how well and how contented the old soldier feels who has his pension coming every month. I had this brought to my notice last week, very forcibly indeed.

In the summer of 1895, when I was running creameries in Mitchell county, I had occasion to help a farmer buy twenty cows. This farmer was almost on the verge of bankruptcy, having a big mortgage on his farm and nothing to pay principal or interest with. He milked very heavily during the years of '95, '96, '97 and '98. He had an average income annually of over twelve hundred dollars from his dairy, and eventually paid off the mortgage and had fifty or sixty cattle on hand.

Mitchell county was then blessed with several good wheat crops, and this man I have in mind, in company with a great many other Kansas farmers, thought that he could make all the money that he would want by raising wheat and fattening cattle. I met this old friend of mine last week and the first thing he asked me was, could I assist him in getting money wherewith to buy fifteen or twenty cows. He said he had plenty of roughness and plenty of fodder and nothing to feed it to. If this gentleman had kept on milking fifteen or twenty cows, if he had continued dairying and diversified farming, if he had not put his dependence entirely on one crop, he would today perhaps have had plenty of money in the bank, been in easy circumstances and able to buy a hundred or five hundred cows if he wanted to do so.

I feel stronger than ever in my belief that neither Kansas nor any other country is adapted to purely grain raising. Any farmer can maintain ten, fifteen or twenty cows on a quarter section, and he can receive from them a steady, reliable income of from six hundred to one thousand dollars per year, and can he wish for better conditions than those?

Farmer boys will go to town to look for work as clerks for salaries of three, four and six hundred dollars per year; yet they have the chance on the farm to earn many times that amount, to live in ease and comfort, to be engaged in the most independent and surest way of making a living that is known to man. I maintain that no state or farming community can be called prosperous until its farmers engage in diversified farming, depending not on one or two grain crops, but depending above all on keeping their herds of cows to which they can feed the fodder and grasses that have their natural home in Kansas. And when that time comes, as surely it will, when the majority of Kansas farmers realize that dairying and diversified farming means prosperity, then Kansas will be the wealthiest and most contented agricultural state in the Union.

Making Cottage Cheese.

[Extract from U. S. Farmers' Bulletin No. 166.]

A toothsome and nutritious article of food is made from sour skim milk or buttermilk by allowing the casein to coagulate by the action of acid already naturally formed, and then expelling the water by the aid of heat. A considerable number of products, locally distinct and different in the degree of dryness of the curd, are made in this way. The general process of manufacture is to take sour buttermilk or skimmed milk which has coagulated, heat it gently from 85 to 125 degrees Fahrenheit, according to circumstances, and drain off the whey through a cloth strainer. Then reduce the texture of the resulting curd by kneading with the hands or a pestle; salt is added, and the produce is improved by the addition of a small quantity of cream or butter. Some persons consider it an improvement to season by the use of one of the more common spices, as nutmeg, caraway, etc, It is largely made only for domestic consumption, but in most cities and villages, especially during the summer months, there is a considerable demand for fresh cheese of this sort, and its manufacture is often a source of revenue to factories suitably located. It is usually sold and eaten in a fresh state, but it may be subjected to certain processes, which quite materially change its character and which vary widely in different localities. This simple kind of cheese is also called Dutch cheese, cottage cheese, and schmierkase.

$500 REWARD FOR WOMEN

WHO CANNOT BE CURED.

Backed up by over a third of a century of remarkable and uniform cures, a record such as no other remedy for the diseases and weaknessess peculiar to women ever attained, the proprietors and makers of Dr. Pierce's Favorite Prescription now feel fully warranted in offering to pay $500 in legal money of the United States, for any case of Leucorrhea, Female Weakness, Prolapsus, or Falling of Womb which they cannot cure. All they ask is a fair and reasonable trial of their means of cure.

They have the most remarkable record of cures made by this world-famed remedy ever placed to the credit of any preparation especially designed for the cure of woman's peculiar ailments.

A beautiful Georgia lady, Vice-President of the East End Palmetto Club, of Savannah, and prominent socially there, relates the following experience: "You certainly have produced the finest medicine for suffering women that is to be had in the country. I want to recommend it especially to mothers. I was seventeen years old when my darling boy was born. Felt very exhausted and weak for a long time, and it seemed I could not get my strength back. My sister-in-law bought me a bottle of Dr. Pierce's Favorite Prescription (after I had tried several of the other remedies which are so much advertised, and found no relief). I had little faith in the medicine at the time and was so weak and sick that I felt discouraged, but within a week after I had commenced taking your 'Prescription' I was like a different woman. New life and vitality seemed to come with each succeeding day, until, in a few weeks, I was in fine health, and a happy, hearty woman. My boy is now two years old, and, thanks to your splendid medicine, I am enjoying perfect health. If at any time I feel tired or in need of a tonic, a few doses of your 'Favorite Prescription' recuperates me at once. My address is No. 511 Jones Street, East, Savannah, Ga.

Our New Patent

and Great sales are the talk of all who know of them. A fortune has been made by the patentee and the farmer in a short time. For seven months the sales were over $350.00 per day. Something good can't be gotten for nothing. By putting $500.00 and upwards into this business it will be the best paying investment we know of. Farmers using the machine say that they would not do without it for two, three, and ten times the price. Common farmer can handle it in a very paying way. We can prove the great selling qualities of this machine by bank account, the bankers themselves, and the farmer. Our plan is fair and honest. Best bank references. Car fare one way will be paid to responsible men whether they iuvest or not. Address

CLARENCE RAGSDALE, Moberly, Mo.

Proprietor of Magic City Stock Farm.

Care of the Cows at Calving Time.

ED. HOARD'S DAIRYMAN:—Frequently dairy farmers are altogether too careless in regard to the treatment of their cows that are carrying calves. This is far from being an unimportant question, as many are inclined to imagine, and should be clearly understood by all those who wish to attain perfection. To begin with, I may state that there are many little items in regard to the management of the pregnant cow, which all dairymen should thoroughly understand, and if these were better understood by those connected with this industry, there would be a marked falling off in the deaths amongst our dairy herds.

It is a very evident fact that when a cow calves, there is a sudden rush of milk into the udder. This must, to a certain degree, cause a shock to the system, which in a great number of cases is the chief factor in causing milk fever. This is probably caused through the animal being too fat and not having sufficient exercise. To prevent this, one must take steps to eradicate this ever prevalent disease.

In the first place, after the animal has proved in calf, and not required any further for milking purposes, she should be put on entirely different diet. At this period it is not necessary to stimulate the milk flow, hence, food required for that purpose would be turned into fat. In cases where cows are used to being stabled, their food should consist of bran mashes, with sufficient linseed cake, to keep the bowels open. While on the other hand, if they are not stable fed, they should be turned out on poorer country immediately their services can be dispensed with in the herd.

Milk fever seems more likely to attack animals that have had several calves, than heifers. If the animal happens to be a very heavy milker, and comes from a breed of cows that have suffered from milk fever, she should have some medicine in addition to the food stated above. During recent years it has been found that the administration of a drachm of iodide of potash in water night and day, for a week previous to calving, is an effective preventive for milk fever; and if the cow is very fat she should have an extra dose prior to calving.

Animals that are unfortunate enough to be paralyzed with the disease are often cured by injecting two drachms of the medicine dissolved in a quart of freshly boiled water, into the udder. Some people at this stage will persist in giving the animal a good dose of Epsom salts; but this is not altogether a good plan, as the unfortunate animal may be choked. When the calf comes, and the cow is not showing any symptons of the disease, no attempt should be made at first to remove the afterbirth, but if does not come away promptly she should be given a good feed of oats as this frequently has the desired effect. If the cleaning does not come away within three hours after this, then it should be removed by hand. The newly calved cow should have sloppy bran mash providing she is stabled.

The milk should not be wholly stripped away at first. The calf sucks but a small portion at first in nature and this is the index for us to follow. For a few days, milk some three times a day, but do not take all the milk to cause a void in the udder which the lacteal glands immediately try to fill up, causing a strain upon the system of the cow. It is better to allow the calf to suck for a few days in cases where the cow is very fat. If the udder does not soften promptly it should be bathed well with hot water three times a day, and castor oil well rubed in. Stabled cows should be fed carefully for at least a week after calving.

"DAIRY SUPERVISION IN AUSTRALIA."

Recently a very great amount of dissatisfaction has been caused amongst the dairymen in this country in regard to the provisions of the proposed new bill for the supervision of dairies and milk production generally. This bill has been drafted by Dr. Gresswell, chairman of the Public Board of Health, and while that respected gentleman may have had good intentions, he contrived to introduce some clauses, if carried out under strict inspection, would I dare say be the means of injuring this thriving industry. That the utmost cleanliness should exist in all dairies and everything pertaining to the production, handling and sale of milk, goes without saying and I must candidly confess that there is great room for improvement in the general management of our dairy herds, and the milking yards and sheds are frequently in a very bad state. But to give the Board of Health the power to make regulations pertaining to the milk, the cow, the men employed, the milking sheds and almost everything in connection with the whole dairyman's plant appears to me to be quite uncalled for.

The industry is not in the position to stand such legislation that will cause unnecessary expense to our dairymen. The production of butter for the past couple of seasons, even in the most favored districts where drought has been unknown, has gone off considerably; and if dairy farmers are forced to have their cows examined twice each year, at their own expense, and those supposed to be suffering from any disease, destroyed, well, I think all those individuals who are possessed of any brains at all, will leave dairying alone. This periodical examination is, of course, intended for a check against the spread of tuberculosis in our dairy herds.

The actual expense involved in making this periodical inspection and test, will probably amount to 10 or 12 shillings per head for the animals operated on, this I should say, is rather expensive for farmers. Another clause of this proposed bill provides that all cow yards, milking sheds, pig styes, etc., must be paved or flagged with brick, stone, cement or asphalt, and shall be provided with suitable drains. This may prove all right in some districts where stone and bricks are plentiful, but in other parts of our country it would mean a very large outlay for the farmers. In trying to accomplish too much in this respect there will be nothing done, hence, it is to be hoped that this industry will not get a reverse that may put it back for a considerable time.

PROPER TIME TO FEED COWS.

The time of day at which dairy cows should be fed, is a matter of more importance than most people are inclined to think. In referring to this subject, my advice applies more to those who run their cows on the pasture and feed at various times during the day. A great many dairy farmers make it a practice to feed their animals either in the morning, when milking operations are going on, or just after the milking is concluded, and again in the evening. The result is, that instead of the cows going away during the intervening time and feeding, they hang round the yard or paddock where the fodder is usually dealt out to them.

This causes them to be unsettled, and the consequence is, that the milk supply is affected. Except in cases where there is no natural fodder, it will be found a wiser plan to only feed once a day and give them that at night after the milking has been accomplished. Those who have tried this plan, find that it acts splendidly. The best plan, I think, is to have a couple of small paddocks near the milking sheds. In these the cows can be turned after they have been milked, and a good supply of food, whatever it may consist of, can be handed out to them. The animals quickly fill themselves, after which they lie down and chew their cud quite contentedly. When they are required for the morning, there is little or no trouble required in mustering them. After they have been milked they go away quite contented to the grass paddock, realizing that they are not to receive any more artificial food until evening comes round. Those who have followed out this plan, find that it gives very satisfactory results.

MANGLES FOR WINTER FEED.

Of all the root crops grown for winter feed for dairy cattle, perhaps none are so satisfactory and so profitable as the mangle where soil and climate are suitable. A few farmers in our state have been in the habit of growing a small area each year, but the practice is not so general as it should be. When fed to cows at the rate of 25 to 30 lbs. per head per day, together with as much good oat straw as can be eaten, the supply of milk during the winter months is maintained at a high level. On fairly good land one can rely on an average crop of, say, 60 tons per acre, and though in bad seasons only 40 tons may be obtained, yet in favorable years up to 90 tons is not an uncommon occurrence.

The first essential in mangle culture, is a piece of good soil in a moist but not wet situation, as the roots have to grow in the summer. The land is plowed in latter end of April or beginning of May, which soon brings up an autumn growth of weeds, and early in spring a scarifying is given, and sufficient harrowing to reduce the soil to a fine tilth. Raised drills about 28 inches apart are made with the hiller, and then the surface is flattened and compressed with the roller. The quantity of seed required, when sown by hand, is about 3 lbs. per acre. A dibble 16 inches long should be used, and with this a small hole is made about half an inch deep, into which two or three seeds are dropped and the earth firmly pressed over them. The distance between the holes should be 16 inches, which is measured by the dibble of that length. Hand sowing may appear a slow and tedious method, but when over 100 tons of roots can be obtained from a couple of acres, the labor cost is comparatively trifling. On large areas the drill should be used. When the plants have been up for a few weeks and are about 5 inches high, they should be thinned out, only leaving one every 16 inches. The plants should be thoroughly cleaned of weeds a couple of times, which is all that is necessary. The roots may be pulled during the month of May. The tops are pulled off and the roots carted to a convenient spot, where they should be piled in heaps about 5 or 6 ft. high. No cover is required, as after being stacked for a few weeks they are better for feeding purposes, becoming a little softer and more easily eaten by stock. Mangles are gross feeders, hence a good supply of manure is very essential for the production of a good crop.

Manure Cellars in Vermont.

A Silo Question.

ED. HOARD'S DAIRYMAN:—John Gould says in HOARD'S DAIRYMAN that he does not see why the New England farmers stick to their manure cellars. I can tell him how he can find out. Let him build a barn with a manure cellar and use it for two years and the problem will be solved. He will then ask the question: How did I ever get along without a manure cellar?

I would like to ask Mr. Gould if he remembers trying to get to Washington, Vt., with the Board of Agriculture, the 19th of February, 1902? Would it have been possible to get into most of our fields to spread manure? And that was not an exceptional day by any means.

We have many such days in the winter. There are three men of us on our farm, all good workers, and there were 30 or 40 days during the winter that all of us could not have kept the road clear, cleaned the stables and spread the manure from 65 head of cattle each day as they come and the manure is not worth near as much as when kept in the cellar and drawn out when wanted.

Then, it is too expensive to hitch up a pair of horses 365 days in a year to draw out one or two loads of manure. When with a manure spreader you can draw out 25 or 30 loads without hitching up of team. In haying it is a great hindrance and on Sundays it is not pleasant and the men do not like to do it.

I would like to ask Mr. Gould if he thinks it would hold to use elm ½ inch sprung round a round silo for hoops to begin at the bottom and cover the outside and nail with 8-penny nails, breaking joints. R. T. D.

Williamstown, Vt.

The American Corn Row.

A Record of Waste.—Nothing Practical About It.

"The American corn row last year reached from the earth to the sun and back again with some million miles to spare, and we harvested just about one-third of the crop, which a wiser agriculture would have given us.

PROF. I. P. ROBERTS."

And yet, every farmer who was one of that great army who raised but a third of a corn crop, or when he had raised that third, wasted a large portion of it by unwise methods of feeding, looks upon himself as a *practical* man. Was ever the word "practical" worse applied than by these men who use it to cover their lack of intelligent methods? In their minds the teachings of knowledge, of experience, of science are nothing but theory, while they are the real practical men of agriculture.

A leading farmer of Pennsylvania once said to us: "I prided myself for years on being a *practical* man, until by some means or other I discovered that I was using the word to cover my own lack of sound knowledge. Since that time I have looked back on my own ignorance of what I could easily have known of good farming methods, had I been a mind to, and feel ashamed to think I ever used the word. It didn't apply to me at all."

Truly we "live and learn" but slowly, and when we come to see that we really need to learn, there are but few years left in which to learn.

70 HEAD PUBLIC SALE 70 HEAD

GREATEST OFFERING OF

HOLSTEIN-FRIESIAN CATTLE.

McADAM & VON HEYNE'S

Justly Celebrated Herd of Holstein-Friesian Cattle will be sold at Public Auction, at Brothertown Stock Farms, Deansboro, N. Y., on

WENDESDAY, JULY 15, 10 O'CLOCK A. M.

SADIE VALE CONCORDIA, THE WORLD'S CHAMPION BUTTER COW, with an official butter test of 30 lbs. 10 2 oz. of butter in seven days, 123 lbs. 10.7 oz. in 30 days, and 220 lbs. 8.4 oz. of butter in 60 days, will go to the highest bidder. Also one of her sons, two daughters, five grand-daughters, two great grand-daughters and two great grand-sons are included in this sale, and placed within the reach of every buyer or breeder.

This sale also includes the famous ex-champion, Mercedes Julip's Pietertje, with an official record of 29 lbs. 5.7 oz. of butter in seven days, her daughter and her grand-daughter.

This Sale Offers to Breeders Three Sires of Very Choicest Breeding

SADIE VALE CONCORDIA'S PAUL DE KOL, No. 27,392, three years old; sire Paul De Kol 4th.; dam, Sadie Vale Concordia, official record 30 lbs. 10.2 oz. butter. This is the world's record for mature cows.

SIR PIETERTJE POSCH, No. 30.155, two years old; dam, Alta Posch, official record 27 lbs. 2.4 oz. butter, at 2 years and 11 months. This is the world's record for two and three year old cows.

CANARY MERCEDES JOHANNA DE KOL, No. 30,251; sire Johanna Rue 2nds. Paul De Kol; dam, Canary Mercedes Brightest, official record 21 lbs. 3 oz. at 2 years and 11 months. His four nearest dams average 23 lbs. 5.6 oz. butter in official record; they also average 4.06 per cent. in butter fat. All cows offered are in calf either to one or the other of the above named bulls. The Herd numbers

70 HEAD OF VERY SUPERIOR ANIMALS,

selected with great care. A large number being from the CELEBRATED YEOMANS HERD. This superiority has been strongly demonstrated, having won in last year's official tests more prizes for large and economical production than any other herd either in the United States or Canada.

In this offering of fine stock are cattle suitable for the best herds, also for the improvement of good herds, as well as cattle for the beginner; as the latter, in buying any of these cattle will start with the most famous and most desirable families, the most important, if not the prime factor in the success of breeding pure bred cattle.

The farms can be reached on the D. L. & W. R. R. to Waterville, N. Y., or the O. & W. R. R. to Deansboro, N. Y., where at either station visitors will be met promptly, on the morning of the sale, and conveyed to the farms. Also the farms can be reached by trolley from Utica to Clinton, N. Y., thence by livery. Catalogues ready early in June. Address

Mc ADAM & VON HEYNE, Deansboro, N. Y.

The sale will commence promptly AT 10 A. M. WEDNESDAY, JULY 15, 1903.

COL. CAREY M. JONES, Auctioneer.

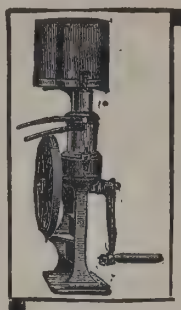
34 cows and heifers in the McGEOCH HERD have been officially tested with the following results: 10 cows average 20.26 lbs. butter in seven days; average per cent of fat 4.06. 7 four-year-olds average 16.82 lbs. butter in seven days; average per cent of butter fat 3.93. 9 three-year-olds average 15.06 lbs of butter in seven days; average per cent of fat 3.50. 8 two-year-olds average 12.16 lbs of butter in seven days; average per cent of fat 3.60. We have a few young bulls out of some of these cows, and sired by Gem Pietertje Hengerveld Paul DeKol, or Sir Ormsby DeKol for sale. One of these is out of a cow that made official record of 24.88 lbs. of butter in seven days, average per cent of fat 4.47. Are these the kind of Holstein-Friesians you wish? If so, can we not interest you in putting a bull from this class of stock at the head of your herd? McGEOCH HERD is located at Lake Mills, Wis., 56 miles west of Milwaukee. For particulars address H. B. Daggett, Mgr., Station A, Milwaukee, Wis Residence: National Ave. near 40th. Phone, South 1601.

How a Cement Silo was Built.

In erecting the cement silo referred to in the article of Mr. Wing in your issue of April 22, I would say that we used the best quality of Portland cement, one part; clean sand, three parts, and screened gravel, five parts, the sand and cement being thoroughly mixed dry, and sufficient water added at the time the gravel was mixed in to make a tolerably thin mortar. We were unable to get gravel with an admixture of sand in the right proportions and consequently were compelled to screen our gravel. We dug a circular ditch the size of the silo 3 feet deep and 1 foot wide. This we filled with mortar to a level with the surface of the ground. Two circular hoops, one 36 feet and the other 38 feet in diameter and 2 feet wide, were then made by nailing half-inch green oak boards on 2×4×3 feet hemlock pieces, which were placed vertically on the inside of the smaller hoop, and on the outside of the larger hoop, were fastened together at the top, 12 inches apart with 2×4 inch cross pieces bolted on. The mould thus made was then set on top of the foundation wall, one hoop on each side thereof and 12 inches apart. After the first filling of the mould, each hoop was cut in three places and a section of about 6 inches taken out of the inside hoop at each place where cut. Draw and extension lugs were then attached to each hoop at each place where they were cut, in such manner that the sections of the inside hoop could be drawn closer together at the points where cut and the sections of the outside hoop pushed apart at such points, thus lessening the diameter of the inside hoop, and increasing the diameter of the outside one. By this manner, after the wall had sufficiently hardened, for which we allowed three days after each filling, the sides of the mould could be loosened from the wall, so that the mould could be easily lifted. The raising of the mould was accomplished by five or six men, each with an improvised lifting jack placed under the cross pieces at the top of the uprights on the mould and resting upon boards placed on the top of the cement wall. By all of them lifting together at the same time the mould could be easily raised and was held in place by putting supports under it at a few points around the wall. These supports were 2×4 in. pieces set upright and resting upon the ground. We tried putting pieces of iron rods under the mould and on top of the wall, but found the uprights preferable. Each time after the mould was raised it would be brought into proper position by tightening the lugs on the outside hoop and extending those on the inside hoop, when filling would again proceed. The mortar was thoroughly settled in the mould with a spade and smooth surfaces of the wall were secured by running the spade up and down the inside edges of the mould after the mortar was put in.



The wall was built to a height of about 6 ft. without scaffolding. In order to make a base for scaffold boards, pieces 2×4 in. and about 5 ft. in length were spiked to the lower end of the studding on the inside hoop and to this extension were spiked two pieces, making an inverted triangle as shown in the figure. The studding on the hoops were placed 2 ft. apart and brackets for scaffolding 4 ft. apart. The scaffolding boards were nailed securely to the top of these brackets. The scaffold was cut at each of the three points where the inside hoop was severed so as to allow the hoop to be contracted at the time of raising the mould after each filling. The mould and scaffolding were thus all connected and all raised together after each filling in the manner described.

Before beginning work on the silo we erected in the center of the site a heavy strong pole about 65 ft. in height made by splicing three telephone poles together. Our silo was to be 52 ft. in height and 36 ft. inside diameter, so we placed on this pole at 50 ft. above the ground, a swinging arm 18 ft in length and attached to the outer end a block and tackle which was operated by a horse and with which the mortar could be raised and landed at any point on the scaffold. Three loops made of wire were attached to the lower block and one of the loops was thrown over the wheel of the wheelbarrow in which the mortar was brought inside the silo, and one over each handle, and in that manner the filled wheelbarrow was raised to the scaffold and landed at any desired point thereon, and the mortar dumped directly from the wheelbarrow into the mould by one man taking hold of the wheelbarrow at the wheel and another at the handles. An ordinary horse could raise all two men could handle in this manner. We laid in the wall about 6 to 8 inches apart strands of oo wire, which is about ⅜ inch in thickness, and has a tensile strength of 8,000 pounds, the ends being passed by each other and doubled back.

The doors were made by setting a wooden frame 2 feet 6 in. by 3 feet with a 3 inch jam into the mould and filling with mortar around it. The bottom of the first door was placed 6 feet above the ground and the bottom of each succeeding door 4 feet from the top of the one immediately below it. To re-enforce the wall at the doors a number of extra wires 10 or 12 feet in length were placed in the wall below, and above each door and extended up and down into the wall at the sides of the doors, the ends of each strand being doubled back onto itself. A temporary door extending to the ground was left at the bottom of the silo to admit the wheelbarrows, and the wires laid in the wall were left long enough at this door, so that when it came to be filled up, after the silo was completed, they could be tied together, thus causing no weakness of the wall at that point.

We used an earth bottom. The inside of the wall, after the silo was finished, was given a heavy coating of coal tar applied as hot as possible. We made a row of doors on opposite sides of the silo and constructed over each a chute extending to the top of the silo, a ladder being made fast to the inside of one chute, and the whole fastened and held by bolts set in the wall as it was building. The silage is thrown from the silo into these chutes from any of the doors and drops directly into the feed wagon.

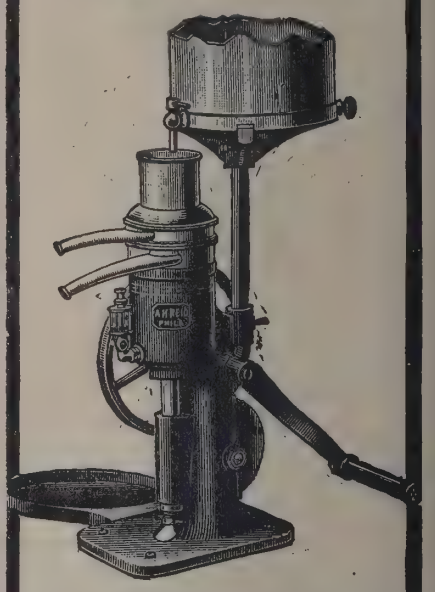
This silo was erected with our ordinary farm labor, two fillings of the wall being made each week, which necessitates extending the work over a period of four months. This method we found very practical, situated as we were, but if one were expecting to employ a special force of men to erect a silo and wanted to push it to completion as rapidly as possible, it would, of course, be best to use continuous cribbing instead of the mould. The cribbing for the whole of a silo, however, would form a considerable item of the cost. If walls thinner than 12 inches were built—and were I building again I should make the walls only 4 or 6 inches thick—continuous cribbing would be required. A closely woven wire screen 2 or 3 feet wide and fitted with draw

YOU DO THE TESTING
on your own farm and make sure you have a bargain and a money maker, when you buy the
AMERICAN CREAM SEPARATOR.
A friend to every man who owns a cow. A machine that is sold on its merits at a surprisingly low price. Get in touch with us. Write for our catalogue. **It Is Free.**
American Separator Company,
Won Medal at Paris in 1900. Box 1023 Bainbridge, N. Y.

THE Iowa Dairy Separator.
AN UP-TO-DATE MACHINE REPLETE WITH PRACTICAL IDEAS
It is built in the following sizes:
250, 350, 450, 600, 750 POUNDS PER HOUR
Our 750 pound per hour machine is a practical Hand Separator. It is as easily run as most separators of 450 pounds and 500 pounds capacity.
SEND FOR CATALOGUE NO. 60 AND PRINTED MATTER.
IOWA DAIRY SEPARATOR COMPANY, WATERLOO, IOWA.

Notice to Dairymen
If you are thinking of buying a Cream Separator write us for Catalogue and information. We manufacture the best machine on the market.
Davis Cream Separator Co.,
54 to 64 N. Clinton St.
CHICAGO, ILL.

NEW OXFORD
BALL BEARING
Cream Separator
Sold on guarantee to be the best on the market. Catalog free.
WORLD CREAM SEPARATOR CO. 41 Main St., Council Bluffs, Ia.



Shepherd's Aerator
is most simple, most effective, least trouble. While you go on milking millions of air globules from the charged tank are passing up through the milk, driving out all animal heat and foreign odors. Works in shipping can. No other vessel to clean. **King among Aerators.** All dairymen prize it. Write for descriptive circular.
F. P. SHEPHERD & CO., Elgin, Ill.

Creasey Ice Breakers

Dairymen and shippers of milk and cream find them most efficient, economical machines, and the greatest savers of time and ice. Easy to operate. Rapid cutters. The design is right.
Made in sixteen sizes to suit every requirement. Send for catalogue "11-B" which gives full particulars.
J. S. L. WHARTON, Mfr.,
7th Clearfield Sts. Philadelphia, Pa.

Reid's Hand SEPARATOR

The "best" separator is that one which does its work most thoroughly and easily, that is built of strongest material, and that is most easily washed and kept in order.
First cost is a great point with a buyer, but ease of running, perfection of skimming and simplicity in washing are even greater considerations.
The **Reid Hand Separator** has but a single cylinder inside the bowl, and skims as closely as one-hundredth of one per cent. Indeed, some tests indicate "not a trace" of fat in the skim milk.
The Reid is perfectly planned and strongly built, and it literally "runs like a watch."
As to our guarantee of excellence, we make the strongest statement that can be expressed in words: **Money back (less freight) if the buyer is not satisfied.**
There is a new (free) booklet about the Reid Hand Separator.
Sizes run from 150 lbs. to 500 lbs. per hour.
A. H. REID
CREAMERY AND DAIRY SUPPLY CO.,
PHILADELPHIA, PA.

MILK WON'T SOUR If you use The Erie Can Refrigerators. An acknowledged Success. Booklet Free.
S. C. SULLIVAN, 425 W. 4th., Erie, Pa.

lugs at two or three points to bring it tightly up against the wall could be used for the outside, and the screen held the proper distance from the inside wall by blocks which could be raised as the mortar was filled in.—HUMPHREY JONES in *Breeder's Gazette.*

Commercial Pepsin in Cheddar Cheese Making.

ED. HOARD'S DAIRYMAN:—In spite of the light thrown on the subject of Cheddar cheese making and ripening by the notable investigations of the Wisconsin and New York (Geneva) Experiment Stations, the manufacture of cheese still continues to be, to a large extent, a "rule of the thumb" process. A great amount of investigational work must yet be done in studying the principles underlying the action of rennet, the function of bacteria, and the chemical and biological changes during curing, before the manufacture of Cheddar cheese can be placed on anything like a scientific basis. One of the chief drawbacks to an understanding of the process is the very meager knowledge we have at present of the composition of the rennet extracts used to coagulate the milk. For some years it seems to have been generally conceded that good rennet can be prepared only from the stomachs of calves, and one frequently meets the statement that rennet extract should be made from "the fourth or digestive stomach of a calf that has not yet ceased to live on milk."

Some of the Danish manufacturers go farther and say that good rennet can be made only from calves that have never had food in their stomachs, and base their claim for the superiority of Danish over American extracts upon the fact that large numbers of such stomachs are obtainable in Denmark, while they cannot be procured in America. These rennet extracts, we are told by the physiologist, contain at least two enzymes, one of which (rennin) coagulates milk but does not digest it, the other (pepsin) digests milk but does not coagulate it. Fleischman mentions still another enzyme that produces lactic acid. Granting the presence of these three enzymes, there are still present, in all probability, a large number of unidentified compounds, so that in reality we know very little of the true composition of rennet extract.

The writer has never felt convinced of the presence of two distinct enzymes, i.e. rennin and pepsin. As these enzymes are to a large extent hypothetical substances it seems that it would have answered the purpose just as well to have ascribed two properties to one body, as to have assumed the presence of two different ones, especially as the enzymes themselves have never been separated in the pure state. In the hope of throwing a little light on the subject of probable existence of one or two enzymes in the stomach, a series of experiments have been conducted by the writer which, while they have made no appreciable addition to the scientific phase of the subject, have taken a practical turn which seems to justify their publication. It may not be out of place to state here, that there are some results, which it is hoped can be added to and published in the near future, that seem to indicate that in fresh preparations made from the stomach lining the rate of coagulation bears a distinct relation to the rate of digestion.

While connected with the Wisconsin Experiment Station, the writer, who was assisting Drs. Babcock and Russell in their investigations on the influence of rennet in cheese ripening, suggested that it be attempted to make cheddar cheese by using commercial scale pepsin as a substitute for rennet extract. Two such cheeses were made and reported briefly in the 17th annual report, page 116. In making them, four (4) grams of scale pepsin dissolved in water was added to 125 pounds of milk. The milk coagulated to a firm curd that cut and acted in every way like the curd produced by rennet. The cheeses were typical high rennet cheese both in appearance and in the character of the chemical by-products. That they resembled high rennet cheese is not surprising in view of the fact that eight times as much pepsin was used as later experiments show to be necessary. Again, the milk where the four grams of pepsin was added coagulated in seven minutes, while the control, to which three ounces of Hansen's Rennet Extract to 1,000 lbs. milk was added, required sixteen minutes to coagulate. In the earlier stages of ripening they were in every way desirable cheeses, but later developed the bitter flavor characteristic of high rennet cheese ripened at high temperatures. When about two months old two of the experts scored the pepsin cheese above the control cheese, not knowing the history of the cheese they were examining.
